  - `type`– Denotes the type of filter. Valid values are `include` and `exclude`. With `include`, the log entry must match the expression to be published to CloudWatch Logs. With `exclude`, each log entry that matches the filter is not sent to CloudWatch Logs.
  - `expression`– A regular expression string that follows the RE2 Syntax.

    Note

    The CloudWatch agent doesn't check the performance of any regular expression that you supply, or restrict the run time of the evaluation of the regular expressions. We recommend that you are careful not to write an expression that is expensive to evaluate. For more information about possible issues, see Regular expression Denial of Service - ReDoS

  For example, the following excerpt of the CloudWatch agent configuration file publishes logs that are PUT and POST requests to CloudWatch Logs, but excluding logs that come from Firefox.

```
"collect_list": [
  {
    "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/test.log",
    "log_group_name": "test.log",
    "log_stream_name": "test.log",
    "filters": [
      {
        "type": "exclude",
        "expression": "Firefox"
      },
      {
        "type": "include",
```

```
        "expression": "P(UT|OST)"
      }
    ]
  },
  .....
]
```

> **Note**
>
> The order of the filters in the configuration file matters for performance. In the preceding example, the agent drops all the logs that match `Firefox` before it starts evaluating the second filter. To cause fewer log entries to be evaluated by more than one filter, put the filter that you expect to rule out more logs first in the configuration file.

- `timezone` – Optional. Specifies the time zone to use when putting timestamps on log events. The valid values are `UTC` and `Local`. The default value is `Local`.

  This parameter is ignored if you don't specify a value for `timestamp_format`.

- `timestamp_format` – Optional. Specifies the timestamp format, using plaintext and special symbols that start with %. If you omit this field, the current time is used. If you use this field, you can use the symbols in the following list as part of the format.

  > **Note**
  >
  > This parameter is not considered when the `file_path` is set to `amazon-cloudwatch-agent.log`

  If a single log entry contains two time stamps that match the format, the first time stamp is used.

  This list of symbols is different than the list used by the older CloudWatch Logs agent. For a summary of these differences, see Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent

`%y`

Year without century as a zero-padded decimal number. For example, 19 to represent 2019.

`%Y`

Year with century as a decimal number. For example, 2019.

`%b`

Month as the locale's abbreviated name

`%B`

Month as the locale's full name

`%m`

Month as a zero-padded decimal number

`%-m`

Month as a decimal number (not zero-padded)

`%d`

Day of the month as a zero-padded decimal number

`%-d`

Day of the month as a decimal number (not zero-padded)

`%A`

Full name of weekday, such as `Monday`

`%a`

Abbreviation of weekday, such as `Mon`

`%H`

Hour (in a 24-hour clock) as a zero-padded decimal number

`%I`

Hour (in a 12-hour clock) as a zero-padded decimal number

`%-I`

Hour (in a 12-hour clock) as a decimal number (not zero-padded)

`%p`

AM or PM

`%M`

Minutes as a zero-padded decimal number

`%-M`

Minutes as a decimal number (not zero-padded)

`%S`

Seconds as a zero-padded decimal number

`%-S`

Seconds as a decimal number (not zero padded)

`%f`

Fractional seconds as a decimal number (1-9 digits), zero-padded on the left.

`%Z`

Time zone, for example PST

`%z`

Time zone, expressed as the offset between the local time zone and UTC. For example, `-0700`. Only this format is supported. For example, `-07:00` isn't a valid format.

- `multi_line_start_pattern` – Specifies the pattern for identifying the start of a log message. A log message is made of a line that matches the pattern and any subsequent lines that don't match the pattern.

  If you omit this field, multi-line mode is disabled, and any line that begins with a non-whitespace character closes the previous log message and starts a new log message.

If you include this field, you can specify `{timestamp_format}` to use the same regular expression as your timestamp format. Otherwise, you can specify a different regular expression for CloudWatch Logs to use to determine the start lines of multi-line entries.

- `encoding` – Specified the encoding of the log file so that it can be read correctly. If you specify an incorrect coding, there might be data loss because characters that can't be decoded are replaced with other characters.

  The default value is `utf-8`. The following are all possible values:

  ```
  ascii, big5, euc-jp, euc-kr, gbk, gb18030, ibm866, iso2022-jp,
  iso8859-2, iso8859-3, iso8859-4, iso8859-5, iso8859-6, iso8859-7,
  iso8859-8, iso8859-8-i, iso8859-10, iso8859-13, iso8859-14,
  iso8859-15, iso8859-16, koi8-r, koi8-u, macintosh, shift_jis, utf-8,
  utf-16, utf-16le, UTF-16, UTF-16LE, windows-874, windows-1250,
  windows-1251, windows-1252, windows-1253, windows-1254,
  windows-1255, windows-1256, windows-1257, windows-1258, x-mac-
  cyrillic
  ```

- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.

- The `windows_events` section specifies the type of Windows events to collect from servers running Windows Server. It includes the following fields:
  - `collect_list` – Required if `windows_events` is included. Specifies the types and levels of Windows events to be collected. Each log to be collected has an entry in this section, which can include the following fields:
    - `event_name` – Specifies the type of Windows events to log. This is equivalent to the Windows event log channel name: for example, `System`, `Security`, `Application`, and so on. This field is required for each type of Windows event to log.

      Note

      When CloudWatch retrieves messages from a Windows log channel, it looks up the log channel based on its `Full Name` property. Meanwhile, the Windows Event Viewer navigation pane displays the `Log Name` property of log channels. The

`Full Name` and `Log Name` do not always match. To confirm the `Full Name` of a channel, right-click on it in the Windows Event viewer and open **Properties**.

- `event_levels` – Optional. Specifies the levels of event to log. You must specify each level to log. Possible values include `INFORMATION`, `WARNING`, `ERROR`, `CRITICAL`, and `VERBOSE`. This field is optional for each type of Windows event to log. and can be used with other filtering option like `event_ids` and `filters`.
- `event_ids` – Optional. Contains an array of Windows Event IDs to specify which events to collect from the Windows Event Log. When this field is excluded, all events from the specified event log are collected. When this field is included, the agent only collects events that match the specified Event IDs.

  Each entry in the `event_ids` array should be a numeric Event ID value and can be used with other filtering options. See the third entry in the config sample below.

  Note

  Using `event_ids` for filtering is recommended over regex expressions when you need to filter by Event ID, as it provides better performance.

- `filters` – Optional. Contains an array of entries. Each entry specifies a regular expression and a filter type to specify whether to publish or drop the log entries that match the filter. When the field is included, the agent processes each log message with all of the filters that you specify, and only the log events that pass all filters are published to CloudWatch Logs. The windows event logs that doesn't pass all of the filters will be dropped and not sent to CloudWatch Logs. The filters section can also be used with other filtering mechanisms like event ids [4624, 4625] and system levels (Information, Error, or Critical) to effectively filter logs and push to CloudWatch.

  Each entry in the filters array can include the following fields:

  - `type` – Specifies the type of filter. Valid values are `include` and `exclude`. With include, the windows events entry must match the expression to be published to CloudWatch Logs. With exclude, each windows event log entry that matches the filter is not sent to CloudWatch Logs.
  - `expression` – A regular expression string that follows the RE2 Syntax.

> **Note**
>
> The CloudWatch agent does not validate regular expressions that you provide. It also does not limit their evaluation time. Write your expressions carefully to avoid performance issues. For more information on security ricks, see Regular expression Denial of Service - ReDoS .

In the example agent configuration below:

For the first entry, the agent pushes logs that contain database failure messages, any authentication related activities, and all login events (both successful and failed attempts) to CloudWatch. Any log that doesn't match this pattern is dropped.

In the second entry, initial filtering is done based on event ids for windows event subscription. The agent collects all logs that contain the string user, discarding logs that don't match these patterns. The agent then drops logs containing `successful` before sending the remaining logs to CloudWatch Logs. Every filter type is applied to each windows event log before sending to CloudWatch.

```
"collect_list": [
  {
        "event_name": "Application",
        "log_group_name": "ApplicationEvents",
        "log_stream_name": "ApplicationEvents",
        "filters": [
            {
                "type": "include",
                "expression": "Database.*failed|Authentication.*|login.*"
            }
        ]
    },
    {
        "event_name": "System",
        "log_group_name": "SystemEvents",
        "log_stream_name": "Logon-events",
        "event_ids": [
            4624,
            4625
         ],
```

```
        "filters": [
            {
                "type": "include",
                "expression": ".*user.*"
            },
            {
                "type": "exclude",
                "expression": ".*successful.*"
            }
         ]
     }
  .....
]
```

> **Note**
>
> The order of the filters in the configuration will impact the performance. In the second entry, the agent drops all the logs that does not match the user before it starts evaluating the second filter expression. For optimal performance, order filters from highest to lowest exclusion rate.

While you can filter out logs on event ids and system levels in the filter expression, it is recommended to use the `event_ids` and `log_level` as shown in the second entry for improved performance.

> **Warning**
>
> Even though all filtering mechanisms (event_levels, event_ids, filters) are optional, at least one is required during agent configuration to filter logs.

- `log_group_name` – Required. Specifies what to use as the log group name in CloudWatch Logs.
- `log_stream_name` – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}` retrieves the hostname from the EC2 metadata, and `{local_hostname}` uses the hostname from the network configuration file.

If you omit this field, the value of the `log_stream_name` parameter in the global `logs` section is used. If that is also omitted, the default value of `{instance_id}` is used.

If a log stream doesn't already exist, it's created automatically.

- `event_format` – Optional. Specifies the format to use when storing Windows events in CloudWatch Logs. `xml` uses the XML format as in Windows Event Viewer. `text` uses the legacy CloudWatch Logs agent format.
- `retention_in_days` – Optional. Specifies the number of days to retain the Windows events in the specified log group.
  - If the agent is creating this log group now, and you omit this field, the retention of this new log group is set to never expire.
  - If this log group already exists and you specify this field, the new retention that you specify is used. If you omit this field for a log group that already exists, the log group's retention is not changed.

    The CloudWatch agent wizard uses `-1` as the default value for this field when it is used to create the agent configuration file and you don't specify a value for log retention. This `-1` value specifies set by the wizard specifies that the events in the log group don't expire. However, manually editing this value to `-1` has no effect.

  Valid values are 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 2192, 2557, 2922, 3288, and 3653.

  If you configure the agent to write multiple log streams to the same log group, specifying the `retention_in_days` in one place will set the log retention for the entire log group. If you specify `retention_in_days` for the same log group in multiple places, the retention is set if all of those values are equal. However, if different `retention_in_days` values are specified for the same log group in multiple places, the log retention will not be set and the agent will stop, returning an error.

  > **Note**
  >
  > The agent's IAM role or IAM user must have the `logs:PutRetentionPolicy` for it to be able to set retention policies.

> **Warning**
>
> If you set `retention_in_days` for a log group that already exists, all logs in that log group that were published before the number of days that you specify are deleted. For example, setting it to 3 would cause all logs from 3 days ago and before to be deleted.

- `log_stream_name` – Optional. Specifies the default log stream name to be used for any logs or Windows events that don't have individual log stream names defined in the `log_stream_name` parameter within their entry in `collect_list`.
- `endpoint_override` – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends logs. Specifying this field and setting a private link enables you to send the logs to an Amazon VPC endpoint. For more information, see What Is Amazon VPC?.

  The value of `endpoint_override` must be a string that is a URL.

  For example, the following part of the logs section of the configuration file sets the agent to use a VPC Endpoint when sending logs.

  ```
  {
    "logs": {
      "endpoint_override": "vpce-XXXXXXXXXXXXXXXXXXXXXXXX.logs.us-
  east-1.vpce.amazonaws.com",
     ......
     },
  }
  ```

- `force_flush_interval` – Specifies in seconds the maximum amount of time that logs remain in the memory buffer before being sent to the server. No matter the setting for this field, if the size of the logs in the buffer reaches 1 MB, the logs are immediately sent to the server. The default value is 5.

  If you are using the agent to report high-resolution metrics in embedded metric format, and you are setting alarms on those metrics, keep this parameter set to the default value of 5. Otherwise, the metrics are reported with a delay that can cause alarming on partial or incomplete data.
- `credentials` – Specifies an IAM role to use when sending logs to a different AWS account. If specified, this field contains one parameter, `role_arn`.

- `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending logs to a different AWS account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this overrides the `role_arn` specified in the `agent` section of the configuration file, if any.

- `metrics_collected` – This field can contain sections to specify that the agent is to collect logs to enable use cases such as CloudWatch Application Signals and Container Insights with enhanced observability for Amazon EKS.
  - `application_signals` (Optional) Specifies that you want to enable CloudWatch Application Signals For more information about this configuration, see Enable CloudWatch Application Signals.
  - `kubernetes` – This field can contain an `enhanced_container_insights` parameter, which you can use to enable Container Insights with enhanced observability for Amazon EKS.
    - `enhanced_container_insights` – Set this to `true` to enable Container Insights with enhanced observability for Amazon EKS. For more information, see Container Insights with enhanced observability for Amazon EKS.
    - `accelerated_compute_metrics` – Set this to `false` to opt out of collecting Nvidia GPU metrics on Amazon EKS clusters. For more information, see NVIDIA GPU metrics.
  - `emf` – To collect metrics embedded in logs, it is no longer necessary to add this `emf` field. This is a legacy field that specified that the agent is to collect logs that are in embedded metric format. You can generate metric data from these logs. For more information, see Embedding metrics within logs.
  - `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.

The following is an example of a `logs` section.

```
"logs":{
    "logs_collected": {
    "files": {
            "collect_list": [
                  {
                       "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\Logs\\amazon-cloudwatch-agent.log",
                     "log_group_name": "amazon-cloudwatch-agent.log",
                     "log_stream_name": "my_log_stream_name_1"
```

```
                    },
                    {
                        "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\Logs\\test.log",
                        "log_group_name": "test.log",
                        "log_stream_name": "my_log_stream_name_2"
                    }
                ]
            },
        "windows_events": {
                 "collect_list": [
                                 {
                        "event_name": "System",
                        "event_ids": [
                            1001,
                            1008
                        ],
                        "log_group_name": "System",
                        "log_stream_name": "System"
                    },
                    {
                        "event_name": "CustomizedName",
                        "event_levels": [
                            "INFORMATION",
                            "ERROR"
                        ],
                        "log_group_name": "CustomizedLogGroup",
                        "log_stream_name": "CustomizedLogStream"
                    },
                    {
                        "event_name": "Application",
                        "event_levels": [
                            "INFORMATION",
                            "ERROR"
                        ],
                        "event_ids":[
                             7369,
                             5624
                        ],
                        "log_group_name": "CustomizedLogGroup",
                        "log_stream_name": "CustomizedLogStream"
                    }
                ]
            }
```

```
       },
       "log_stream_name": "my_log_stream_name",
       "metrics_collected": {
        "kubernetes": {
        "enhanced_container_insights": true
      }
    }
  }
```

CloudWatch agent configuration file: Traces section

By adding a `traces` section to the CloudWatch agent configuration file, you can enable CloudWatch Application Signals or collect traces from X-Ray and from the OpenTelemetry instrumentation SDK and send them to X-Ray.

> **Important**
>
> The agent's IAM role or IAM user must have the **AWSXrayWriteOnlyAccess** policy to send trace data to X-Ray.

For a quick start for collecting traces, you can add just the following to the CloudWatch agent configuration file.

```
"traces_collected": {
        "xray": {
        },
        "otlp": {
        }
      }
```

If you add the previous section to the CloudWatch agent configuration file and restart the agent, this causes the agent to start collecting traces using the following default options and values. For more information about these parameters, see the parameter definitions later in this section.

```
"traces_collected": {
        "xray": {
            "bind_address": "127.0.0.1:2000",
            "tcp_proxy": {
              "bind_address": "127.0.0.1:2000"
            }
```

```
        },
        "otlp": {
            "grpc_endpoint": "127.0.0.1:4317",
            "http_endpoint": "127.0.0.1:4318"
        }
    }
```

The `traces` section can include the following fields:

- `traces_collected` – Required if the `traces` section is included. Specifies which SDKs to collect traces from. It can include the following fields:
  - `application_signals` – Optional. Specifies that you want to enable CloudWatch Application Signals For more information about this configuration, see Enable CloudWatch Application Signals.
  - `xray` – Optional. Specifies that you want to collect traces from the X-Ray SDK. This section can include the following fields:
    - `bind_address` – Optional. Specifies the UDP address for the CloudWatch agent to use to listen for X-Ray traces. The format is `ip:port`. This address must match the address set in the X-Ray SDK.

      If you omit this field, the default of `127.0.0.1:2000` is used.
    - `tcp_proxy` – Optional. Configures the address for a proxy used to support X-Ray remote sampling. For more information, see Configuring sampling rules in the X-Ray documentation.

      This section can contain the following field.
      - `bind_address` – Optional. Specifies the TCP address to which the CloudWatch agent should set up the proxy. The format is `ip:port`. This address must match the address set in the X-Ray SDK.

        If you omit this field, the default of `127.0.0.1:2000` is used.
  - `otlp` – Optional. Specifies that you want to collect traces from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry). For more information about the AWS Distro for OpenTelemetry, see AWS Distro for OpenTelemetry. For more information about the AWS Distro for OpenTelemetry SDKs, see Introduction.

    This section can include the following fields:

    - `grpc_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry traces sent using gRPC Remote Procedure Calls. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK.

      If you omit this field, the default of `127.0.0.1:4317` is used.

    - `http_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OTLP traces sent over HTTP. The format is `ip:port`. This address must match the address set for the HTTP exporter in the OpenTelemetry SDK.

      If you omit this field, the default of `127.0.0.1:4318` is used.

- `concurrency` – Optional. Specifies the maximum number of concurrent calls to X-Ray that can be used to upload traces. The default value is 8
- `local_mode` – Optional. If `true`, the agent doesn't collect Amazon EC2 instance metadata. The default is `false`
- `endpoint_override` – Optional. Specifies a FIPS endpoint or private link to use as the endpoint where the CloudWatch agent sends traces. Specifying this field and setting a private link enables you to send the traces to an Amazon VPC endpoint. For more information, see What is Amazon VPC

  The value of `endpoint_override` must be a string that is a URL.
- `region_override` – Optional. Specifies the Region to use for the X-Ray endpoint. The CloudWatch agent sends the traces to X-Ray in the specified Region. If you omit this field, the agent sends the traces to the Region where the Amazon EC2 instance is located.

  If you specify a Region here, it takes precedence over the setting of the `region` parameter in the `agent` section of the configuration file.
- `proxy_override` – Optional. Specifies the proxy server address for the CloudWatch agent to use when sending requests to X-Ray. The proxy server's protocol must be specified as part of this address.
- `credentials` – Specifies an IAM role to use when sending traces to a different AWS account. If specified, this field contains one parameter, `role_arn`.
    - `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending traces to a different AWS account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this overrides the `role_arn` specified in the `agent` section of the configuration file, if any.

- `transit_spans_in_otlp_format` – Optional. If `true`, sends traces to X-Ray in the OpenTelemetry Protocol format, which supports span events in Transaction Search. For more information, see Adding custom attributes. The default is `false`.

CloudWatch agent configuration file: Complete examples

The following is an example of a complete CloudWatch agent configuration file for a Linux server.

The items listed in the `measurement` sections for the metrics you want to collect can either specify the complete metric name such or just the part of the metric name that will be appended to the type of resource. For example, specifying either `reads` or `diskio_reads` in the `measurement` section of the `diskio` section will cause the `diskio_reads` metric to be collected.

This example includes both ways of specifying metrics in the `measurement` section.

```
   {
     "agent": {
       "metrics_collection_interval": 10,
       "logfile": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log"
     },
     "metrics": {
       "namespace": "MyCustomNamespace",
       "metrics_collected": {
         "cpu": {
           "resources": [
             "*"
           ],
           "measurement": [
             {"name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit":
"Percent"},
             {"name": "cpu_usage_nice", "unit": "Percent"},
             "cpu_usage_guest"
           ],
           "totalcpu": false,
           "metrics_collection_interval": 10,
           "append_dimensions": {
             "customized_dimension_key_1": "customized_dimension_value_1",
             "customized_dimension_key_2": "customized_dimension_value_2"
           }
         },
         "disk": {
           "resources": [
```

```
            "/",
            "/tmp"
          ],
          "measurement": [
            {"name": "free", "rename": "DISK_FREE", "unit": "Gigabytes"},
            "total",
            "used"
          ],
           "ignore_file_system_types": [
            "sysfs", "devtmpfs"
          ],
          "metrics_collection_interval": 60,
          "append_dimensions": {
            "customized_dimension_key_3": "customized_dimension_value_3",
            "customized_dimension_key_4": "customized_dimension_value_4"
          }
        },
        "diskio": {
          "resources": [
            "*"
          ],

              {
                "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/test.log",
                "log_group_name": "test.log",
                "log_stream_name": "test.log",
                "timezone": "Local"
              }
            ]
          }
        },
        "log_stream_name": "my_log_stream_name",
        "force_flush_interval" : 15,
        "metrics_collected": {
           "kubernetes": {
                "enhanced_container_insights": true
      }
    }
  }
}
```

The following is an example of a complete CloudWatch agent configuration file for a server running Windows Server.

```
{
      "agent": {
        "metrics_collection_interval": 60,
        "logfile": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\Logs\\amazon-
cloudwatch-agent.log"
      },
      "metrics": {
        "namespace": "MyCustomNamespace",
        "metrics_collected": {
          "Processor": {
            "measurement": [
              {"name": "% Idle Time", "rename": "CPU_IDLE", "unit": "Percent"},
              "% Interrupt Time",
              "% User Time",
              "% Processor Time"
```

```
            ],
            "resources": [
              "*"
            ],
            "append_dimensions": {

        },
        "log_stream_name": "example_log_stream_name"
      }
    }
```

Save the CloudWatch agent configuration file manually

If you create or edit the CloudWatch agent configuration file manually, you can give it any name. After you have created the file, you can copy it to other servers where you want to run the agent.

Uploading the CloudWatch agent configuration file to Systems Manager Parameter Store

If you plan to use the SSM Agent to install the CloudWatch agent on servers, after you manually edit the CloudWatch agent configuration file, you can upload it to Systems Manager Parameter Store. To do so, use the Systems Manager `put-parameter` command.

To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions.

Use the following command, where *parameter name* is the name to be used for this file in Parameter Store and *configuration_file_pathname* is the path and file name of the configuration file that you edited.

```
aws ssm put-parameter --name "parameter name" --type "String" --value
 file://configuration_file_pathname
```

Enable CloudWatch Application Signals

Use CloudWatch Application Signals to automatically instrument your applications on AWS so that you can track application performance against your business objectives. Application Signals provides you a unified, application-centric view of your Java applications, their dependencies, and their edges. For more information, see Application Signals.

CloudWatch Application Signals leverages the CloudWatch agent to receive metrics and traces from your auto-instrumented applications, optionally apply rules to reduce high cardinality, and then publish the processed telemetry to CloudWatch. You can provide custom configuration to the CloudWatch agent specifically for Application Signals using the agent configuration file. To start with, the presence of an `application_signals` section under the `metrics_collected` section within the `logs` section of the agent configuration file specifies that the CloudWatch agent will receive metrics from your auto-instrumented applications. Similarly, the presence of an `application_signals` section under the `traces_collected` section within the `traces` section of the agent configuration file specifies that the CloudWatch agent is enabled to receive traces from your auto-instrumented applications. In addition, you can optionally pass in custom configuration rules to reduce publishing high-cardinality telemetry as outlined in this section.

- For Amazon EKS clusters, when you install the Amazon CloudWatch Observability EKS add-on, the CloudWatch agent is by default enabled to receive both metrics and traces from your auto-instrumented applications. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration to the Amazon EKS add-on when you create or update it by using additional configuration, as outlined in (Optional) Additional configuration.
- For RedHat for OpenShift on AWS (ROSA), when you install the CloudWatch agent operator using helm charts, the CloudWatch agent is by default enabled to receive both metrics and traces from your auto-instrumented applications. If you would like to optionally pass in custom

configuration rules, you can do so by passing in a custom agent configuration by using the Helm chart, as outlined in (Optional) Additional configuration.

- For other supported platforms including Amazon EC2, you must start the CloudWatch agent with an agent configuration that enables Application Signals by specifying the `application_signals` sections and optionally any custom configuration rules as outlined later in this section.

The following is an overview of the fields in the CloudWatch agent configuration file that are related to CloudWatch Application Signals.

- `logs`
  - `metrics_collected` – This field can contain sections to specify that the agent is to collect logs to enable use cases such as CloudWatch Application Signals and Container Insights with enhanced observability for Amazon EKS.

    > **Note**
    >
    > Previously this section was also used to specify that the agent is to collect logs that are in embedded metric format. Those settings are no longer needed.

    - `application_signals` (Optional) Specifies that you want to enable CloudWatch Application Signals to receive metrics from your auto-instrumented applications to facilitate CloudWatch Application Signals.
      - `rules` (Optional) An array of rules to conditionally select metrics and traces and apply actions to handle high-cardinality scenarios. Each rule can contain the following fields:
        - `rule_name` (Optional) The name of the rule.
        - `selectors` (Optional) An array of metrics and traces dimension matchers. Each selector must provide the following fields:
          - `dimension` Required if `selectors` is not empty. This specifies the dimension of metrics and traces to use as a filter.
          - `match` Required if `selectors` is not empty. A wildcard pattern used for matching values of the specified dimension.
        - `action` (Optional) The action to be applied to metrics and traces that match the specified selectors. The value of `action` must be one of the following keywords:

        - `keep` Specifies to send only the metrics and traces to CloudWatch if matched by the `selectors`.
        - `drop` Specifies to drop the metric and traces that match the `selectors`.
        - `replace` Specifies to replace the dimensions of the metrics and traces that match `selectors`. They are replaced according to the `replacements` section.
      - `replacements` Required if `action` is `replace`. An array of dimension and value pairs that will be applied to metrics and traces that match the specified `selectors` when the `action` is `replace`. Each replacement must provide the following fields:
        - `target_dimension` Required if `replacements` is not empty. Specifies the dimension that needs to be replace.
        - `value` Required if `replacements` is not empty. The value to replace the original value of `target_dimension` with.
    - `limiter` (Optional) Use this section to limit how many metrics and dimensions Application Signals sends to CloudWatch, to optimize your costs.
      - `disabled` (Optional) If `true`, the metric limiting feature is disabled. The default is `false`
      - `drop_threshold` (Optional) The maximum number of distinct metrics per service in one rotation interval that can be exported by one CloudWatch agent. The default is 500.
      - `rotation_interval` (Optional) The interval at which the limiter resets the metric records for distinction counting. This is expressed as a string with a sequence of numbers and a unit suffix. Fractions are supported. The supported unit suffixes are `s`, `m`, `h`, `ms`, `us`, and `ns`

        The default is `1h` for one hour.
      - `log_dropped_metrics` (Optional) Specifies whether the agent should write logs to the CloudWatch agent logs when Application Signals metrics are dropped. The default is `false`.

        > **Note**
        >
        > To activate this logging, the `debug` parameter in the `agent` section must also be set to `true`.

- `traces`
  - `traces_collected`

- `application_signals` Optional. Specify this to enable the CloudWatch agent to receive traces from your auto-instrumented applications for facilitating CloudWatch Application Signals.

> **Note**
>
> Even though the custom `application_signals` rules are specified under the `metrics_collected` section that is contained in the `logs` section, they also implicitly apply to the `traces_collected` section as well. The same set of rules will apply to both metrics and traces.

When there are multiple rules with different actions, they apply in the following sequence: `keep`, then `drop`, then `replace`.

The following is an example of a full CloudWatch agent configuration file that applies custom rules.

```
{
  "logs": {
    "metrics_collected": {
      "application_signals": {
        "rules": [
          {
            "rule_name": "keep01",
            "selectors": [
              {
                "dimension": "Service",
                "match": "pet-clinic-frontend"
              },
              {
                "dimension": "RemoteService",
                "match": "customers-service"
              }
            ],
            "action": "keep"
          },
          {
            "rule_name": "drop01",
            "selectors": [
```

```
              {
                "dimension": "Operation",
                "match": "GET /api/customer/owners/*"
              }
            ],
            "action": "drop"
          },
          {
            "rule_name": "replace01",
            "selectors": [
              {
                "dimension": "Operation",
                "match": "PUT /api/customer/owners/*/pets/*"
              },
              {
                "dimension": "RemoteOperation",
                "match": "PUT /owners"
              }
            ],
            "replacements": [
              {
                "target_dimension": "Operation",
                "value": "PUT /api/customer/owners/{ownerId}/pets{petId}"
              }
            ],
            "action": "replace"
          }
        ]
      }
    }
  },
  "traces": {
    "traces_collected": {
      "application_signals": {}
    }
  }
}
```

For the previous example configuration file, the `rules` are processed as follows:

1. Rule `keep01` ensures that any metrics and traces with the dimension `Service` as `pet-clinic-frontend` and the dimension `RemoteService` as `customers-service` are kept.

2. For the processed metrics and traces after applying `keep01`, the `drop01` rule ensures that metrics and traces with the dimension `Operation` as `GET /api/customer/owners/*` are dropped.
3. For the processed metrics and traces after applying `drop01`, the `replace01` rule updates metrics and traces that have the dimension `Operation` as `PUT /api/customer/owners/*/pets/*` and the dimension `RemoteOperation` as `PUT /owners` such that their `Operation` dimension is now replaced to be `PUT /api/customer/owners/{ownerId}/pets{petId}`.

The following is a complete example of a CloudWatch configuration file that manages cardinality in Application Signals by changing the metric limit to 100, enabling the logging of dropped metrics, and setting the rotation interval to two hours.

```
{
    "logs": {
        "metrics_collected": {
            "application_signals": {
                "limiter": {
                    "disabled": false,
                    "drop_threshold": 100,
                    "rotation_interval": "2h",
                    "log_dropped_metrics": true
                }
            }
        },
        "traces": {
            "traces_collected": {

            }
        }
    }
}
```

Collect network performance metrics

EC2 instances running on Linux that use the Elastic Network Adapter (ENA) publish network performance metrics. Version 1.246396.0 and later of the CloudWatch agent enable you to import these network performance metrics into CloudWatch. When you import these network performance metrics into CloudWatch, they are charged as CloudWatch custom metrics.

For more information about the ENA driver, see Enabling enhanced networking with the Elastic Network Adapter (ENA) on Linux instances and Enabling enhanced networking with the Elastic Network Adapter (ENA) on Windows instances.

How you set up the collection of network performance metrics differs on Linux servers and Windows servers.

The following table lists these network performance metrics enabled by the ENA adapter. When the CloudWatch agent imports these metrics into CloudWatch from Linux instances, it prepends `ethtool_` at the beginning of each of these metric names.

Metric	Description
Name on Linux servers: **`bw_in_allowance_exceeded`** Name on Windows servers: **`Aggregate inbound BW allowance exceeded`**	The number of packets queued and/or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers: **`bw_out_allowance_exceeded`** Name on Windows servers: **`Aggregate outbound BW allowance exceeded`**	The number of packets queued and/or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers:**`conntrack_allowance_available`**	Reports the number of tracked connections that can be established by the instance before hitting

Metric	Description
Name on Windows servers: **`Available connection tracking allowance`**	the Connections Tracked allowance of that instance type. This metric is available only on Nitro-based EC2 instances using the Linux driver for Elastic Network Adapter (ENA) starting from version 2.8.1, and on computers using the Windows driver for Elastic Network Adapter (ENA) starting from version 2.6.0. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers:**`ena_srd_mode`** Name on Windows servers: **`ena srd mode`**	Describes which ENA Express features are enabled. For more information about ENA Express, see Improve network performance with ENA Express on Linux instances Values are as follows: • `0` = ENA Express off, UDP off • 1 = ENA Express on, UDP off • 2 = ENA Express off, UDP on **Note** This happens only when ENA Express was originally enabled, and UDP was configured to use it. The prior value is retained for UDP traffic. • 3 = ENA Express on, UDP on

Metric	Description
Name on Linux servers:**ena_srd_eligible_tx_pkts** Name on Windows servers: **ena srd eligible tx pkts**	The number of network packets sent within a given time period that meet AWS Scalable Reliable Datagram (SRD) requirements for eligibility, as follows: • Both sending and receiving instance types are supported. • Both sending and receiving instances must have ENA Express configured. • The sending and receiving instances must be on the same subnet. • The network path between the instances must not include middleware boxes. ENA Express doesn't currently support middleware boxes.
Name on Linux servers:**ena_srd_tx_pkts** Name on Windows servers: **ena srd tx pkts**	The number of SRD packets transmitted within a given time period.
Name on Linux servers:**ena_srd_rx_pkts** Name on Windows servers: **ena srd rx pkts**	The number of SRD packets received within a given time period.
Name on Linux servers:**ena_srd_resource_utilization** Name on Windows servers: **ena srd resource utilization**	The percentage of the maximum allowed memory utilization for concurrent SRD connections that the instance has consumed.

Metric	Description
Name on Linux servers: **`linklocal_allowance_exceeded`** Name on Windows servers: **`Link local packet rate allowance exceeded`**	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service, but does not impact traffic to custom DNS resolvers. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers: **`pps_allowance_exceeded`** Name on Windows servers: **`PPS allowance exceeded`**	The number of packets queued and/or dropped because the bidirectional PPS exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Linux setup

On Linux servers, the *ethtool plugin* enables you to import the network performance metrics into CloudWatch.

ethtool is a standard Linux utility that can collect statistics about Ethernet devices on Linux servers. The statistics it collects depend on the network device and driver. Examples of these statistics include `tx_cnt`, `rx_bytes`, `tx_errors`, and `align_errors`. When you use the ethtool plugin

with the CloudWatch agent, you can also import these statistics into CloudWatch, along with the EC2 network performance metrics listed earlier in this section.

> **Tip**
>
> To find the statistics available on our operating system and network device, use the `ethtool -S` command.

When the CloudWatch agent imports metrics into CloudWatch, it adds an `ethtool_` prefix to the names of all imported metrics. So the standard ethtool statistic `rx_bytes` is called `ethtool_rx_bytes` in CloudWatch, and the EC2 network performance metric `bw_in_allowance_exceeded` is called `ethtool_bw_in_allowance_exceeded` in CloudWatch.

On Linux servers, to import ethtool metrics, add an `ethtool` section to the `metrics_collected` section of the CloudWatch agent configuration file. The `ethtool` section can include the following subsections:

- **interface_include**— Including this section causes the agent to collect metrics from only the interfaces that have names listed in this section. If you omit this section, metrics are collected from all Ethernet interfaces that aren't listed in `interface_exclude`.

  The default ethernet interface is `eth0`.
- **interface_exclude**— If you include this section, list the Ethernet interfaces that you don't want to collect metrics from.

  The ethtool plugin always ignores loopback interfaces.
- **metrics_include**— This section lists the metrics to import into CloudWatch. It can include both standard statistics collected by ethtool and Amazon EC2 high-resolution network metrics.

The following example displays part of the CloudWatch agent configuration file. This configuration collects the standard ethtool metrics `rx_packets` and `tx_packets`, and the Amazon EC2 network performance metrics from only the `eth1` interface.

For more information about the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

```
{
```

```
"metrics": {
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "ethtool": {
        "interface_include": [
          "eth1"
        ],
        "metrics_include": [
          "bw_in_allowance_exceeded",
          "bw_out_allowance_exceeded",
          "conntrack_allowance_exceeded",
          "linklocal_allowance_exceeded",
          "pps_allowance_exceeded"
         ]
      }
   }
}
}
```

Windows setup

On Windows servers, the network performance metrics are available through Windows Performance Counters, which the CloudWatch agent already collects metrics from. So you do not need a plugin to collect these metrics from Windows servers.

The following is a sample configuration file to collect network performance metrics from Windows. For more information about editing the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

```
{
    "metrics": {
        "append_dimensions": {
            "InstanceId": "${aws:InstanceId}"
        },
        "metrics_collected": {
            "ENA Packets Shaping": {
                "measurement": [
                    "Aggregate inbound BW allowance exceeded",
                    "Aggregate outbound BW allowance exceeded",
                    "Connection tracking allowance exceeded",
                    "Link local packet rate allowance exceeded",
```

```
                    "PPS allowance exceeded"
                ],
                "metrics_collection_interval": 60,
                "resources": [
                    "*"
                ]
            }
        }
    }
}
```

Viewing network performance metrics

After importing network performance metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view ethtool metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

Because all of these metrics are aggregate counters, you can use CloudWatch metric math functions such as `RATE(METRICS())` to calculate the rate for these metrics in graphs or use them to set alarms. For more information about metric math functions, see Using math expressions with CloudWatch metrics.

To view network performance metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    b. To sort the table, use the column heading.

    c. To filter by resource, choose the resource ID, and then choose **Add to search**.

    d. To filter by metric, choose the metric name, and then choose **Add to search**.

6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, and then choose **Add to dashboard**.

Collect Amazon EBS NVMe driver metrics

For CloudWatch agent to collect AWS NVMe driver metrics for Amazon EBS volumes attached to an Amazon EC2 instance, add the `diskio` section inside the `metrics_collected` section of the CloudWatch agent configuration file.

Additionally, the CloudWatch agent binary requires `ioctl` permissions for NVMe driver devices to collect metrics from attached Amazon EBS volumes.

The following metrics can be collected.

Metric	Metric name in CloudWatch	Description
`ebs_total_read_ops`	`diskio_ebs_total_read_ops`	The total number of completed read operations.
`ebs_total_write_ops`	`diskio_ebs_total_write_ops`	The total number of completed write operations.
`ebs_total_read_bytes`	`diskio_ebs_total_read_bytes`	The total number of read bytes transferred.
`ebs_total_write_bytes`	`diskio_ebs_total_write_bytes`	The total number of write bytes transferred.
`ebs_total_read_time`	`diskio_ebs_total_read_time`	The total time spent, in microseconds, by all completed read operations.
`ebs_total_write_time`	`diskio_ebs_total_write_time`	The total time spent, in microseconds, by all completed write operations.

Metric	Metric name in CloudWatch	Description
ebs_volume_performance_exceeded_iops	diskio_ebs_volume_performance_exceeded_iops	The total time, in microseconds, that IOPS demand exceeded the volume's provisioned IOPS performance.
ebs_volume_performance_exceeded_tp	diskio_ebs_volume_performance_exceeded_tp	The total time, in microseconds, that throughput demand exceeded the volume's provisioned throughput performance.
ebs_ec2_instance_performance_exceeded_iops	diskio_ebs_ec2_instance_performance_exceeded_iops	The total time, in microseconds, that the EBS volume exceeded the attached Amazon EC2 instance's maximum IOPS performance.
ebs_ec2_instance_performance_exceeded_tp	diskio_ebs_ec2_instance_performance_exceeded_tp	The total time, in microseconds, that the EBS volume exceeded the attached Amazon EC2 instance's maximum throughput performance.
ebs_volume_queue_length	diskio_ebs_volume_queue_length	The number of read and write operations waiting to be completed.

Collect Amazon EC2 instance store volume NVMe driver metrics

For CloudWatch agent to collect AWS NVMe driver metrics for instance store volumes attached to an Amazon EC2 instance, add the `diskio` section inside the `metrics_collected` section of the CloudWatch agent configuration file.

Additionally, the CloudWatch agent binary requires `ioctl` permissions for NVMe driver devices to collect metrics from attached instance store volumes.

The following metrics can be collected.

Metric	Metric name in CloudWatch	Description
instance_store_total_read_ops	diskio_instance_store_total_read_ops	The total number of completed read operations.
instance_store_total_write_ops	diskio_instance_store_total_write_ops	The total number of completed write operations.
instance_store_total_read_bytes	diskio_instance_store_total_read_bytes	The total number of read bytes transferred.
instance_store_total_write_bytes	diskio_instance_store_total_write_bytes	The total number of write bytes transferred.
instance_store_total_read_time	diskio_instance_store_total_read_time	The total time spent, in microseconds, by all completed read operations.
instance_store_total_write_time	diskio_instance_store_total_write_time	The total time spent, in microseconds, by all completed write operations.
instance_store_performance_exceeded_iops	diskio_instance_store_performance_exceeded_iops	The total time, in microseconds, that IOPS demand exceeded the volume's IOPS maximum performance.

Metric	Metric name in CloudWatch	Description
instance_store_performance_exceeded_tp	diskio_instance_store_performance_exceeded_tp	The total time, in microseconds, that throughput demand exceeded the volume's maximum throughput performance.
instance_store_volume_queue_length	diskio_instance_store_volume_queue_length	The number of read and write operations waiting to be completed.

Collect NVIDIA GPU metrics

You can use the CloudWatch agent to collect NVIDIA GPU metrics from Linux servers. To set this up, add a `nvidia_gpu` section inside the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Linux section.

Additionally, the instance must have an NVIDIA driver installed. NVIDIA drivers on pre-installed on some Amazon Machine Images (AMIs). Otherwise, you can manually install the driver. For more information, see Install NVIDIA drivers on Linux instances.

The following metrics can be collected. All of these metrics are collected with no CloudWatch `Unit`, but you can specify a unit for each metric by adding a parameter to the CloudWatch agent configuration file. For more information, see Linux section.

Metric	Metric name in CloudWatch	Description
utilization_gpu	nvidia_smi_utilization_gpu	The percentage of time over the past sample period during which one or more kernals on the GPU was running.
temperature_gpu	nvidia_smi_temperature_gpu	The core GPU temperature in degrees Celsius.

Metric	Metric name in CloudWatch	Description
power_draw	nvidia_smi_power_draw	The last measured power draw for the entire board, in watts.
utilization_memory	nvidia_smi_utilization_memory	The percentage of time over the past sample period during which global (device) memory was being read or written.
fan_speed	nvidia_smi_fan_speed	The percentage of maximum fan speed that the device's fan is currently intended to run at.
memory_total	nvidia_smi_memory_total	Reported total memory, in MB.
memory_used	nvidia_smi_memory_used	Memory used, in MB.
memory_free	nvidia_smi_memory_free	Memory free, in MB.
pcie_link_gen_current	nvidia_smi_pcie_link_gen_current	The current link generation.
pcie_link_width_current	nvidia_smi_pcie_link_width_current	The current link width.
encoder_stats_session_count	nvidia_smi_encoder_stats_session_count	Current number of encoder sessions.
encoder_stats_average_fps	nvidia_smi_encoder_stats_average_fps	The moving average of the encode frames per second.

Metric	Metric name in CloudWatch	Description
encoder_stats_average_latency	nvidia_smi_encoder_stats_average_latency	The moving average of the encode latency in microseconds.
clocks_current_graphics	nvidia_smi_clocks_current_graphics	The current frequency of the graphics (shader) clock.
clocks_current_sm	nvidia_smi_clocks_current_sm	The current frequency of the Streaming Multiprocessor (SM) clock.
clocks_current_memory	nvidia_smi_clocks_current_memory	The current frequency of the memory clock.
clocks_current_video	nvidia_smi_clocks_current_video	The current frequency of the video (encoder plus decoder) clocks.

All of these metrics are collected with the following dimensions:

Dimension	Description
index	A unique identifier for the GPU on this server. Represents the NVIDIA Management Library (NVML) index of the device.

Dimension	Description
name	The type of GPU. For example, NVIDIA Tesla A100
arch	The server architecture.

Collect Java Management Extensions (JMX) metrics

You can use the CloudWatch agent to collect Java Management Extensions (JMX) metrics from your Java applications.

The CloudWatch agent supports collecting these metrics from the following versions:

- JVM 8 and later
- Kafka 0.8.2.x and later
- Tomcat 9, 10.1, and 11 (beta)

Amazon EC2

To enable JMX in your JVM instance

For the CloudWatch agent to be able to collect JMX metrics, your application's JVM must bind to a port using the `com.sun.management.jmxremote.port` system property.

```
java -Dcom.sun.management.jmxremote.port=port-number -jar example.jar
```

For more information and other configurations, see the JMX documentation.

Amazon EKS

To enable JMX on your Java application pods

When using the CloudWatch Observability EKS add-on, you can manage how JMX metrics are enabled with annotations. For more information, see Install the CloudWatch agent with

the Amazon CloudWatch Observability EKS add-on or the Helm chart. To enable JMX metrics collection from a workload, add the following annotations to the workload manifest file under the `PodTemplate` section:

- `instrumentation.opentelemetry.io/inject-java: "true"`
- One or more of the following:
  - For JVM metrics: `cloudwatch.aws.amazon.com/inject-jmx-jvm: "true"`
  - For Kafka broker metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka: "true"`
  - For Kafka consumer metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka-consumer: "true"`
  - For Kafka producer metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka-producer: "true"`
  - For Tomcat metrics: `cloudwatch.aws.amazon.com/inject-jmx-tomcat: "true"`

To start collecting JMX metrics, add a `jmx` section inside the `metrics_collected` section of the CloudWatch agent configuration file. The `jmx` section can contain the following fields.

- `jvm` – Optional. Specifies that you want to retrieve Java Virtual Machine (JVM) metrics from the instance. For more information, see Collect JVM metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of JVM metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect JVM metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `kafka` – Optional. Specifies that you want to retrieve Apache Kafka broker metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

- `measurement` – Specifies the array of Kafka broker metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the first table in Collect Kafka metrics.

  Within the entry for each individual metric, you can optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka-consumer` – Optional. Specifies that you want to retrieve Apache Kafka consumer metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka broker metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the second metrics table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka-producer` – Optional. Specifies that you want to retrieve Apache Kafka producer metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka broker metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the third metrics table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.

    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `tomcat` – Optional. Specifies that you want to retrieve Tomcat metrics from the instance. For more information, see Collect Tomcat metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Tomcat metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect Tomcat metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

The `jmx` section can also include the optional `append_dimensions` field:

- `append_dimensions` – Optional. Additional dimensions to use for only the process metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

The following fields are for Amazon EC2 only.

- `endpoint` – The address for the JMX client to connect to. The format is `ip:port`. If the endpoint is not the localhost, and password authentication and SSL must be enabled.
- `metrics_collection_interval` – Optional. Specifies how often to collect the processes metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

If JMX was enabled with password authentication or SSL for remote access, you can use the following fields.

- `password_file` – Optional. Specifies a Java properties file of keys to passwords. The file must be read-only and restricted to the user running the CloudWatch agent. If password authentication is enabled, this requires the same username and password pair as the entry in the JMX password file provided in the `com.sun.management.jmxremote.password.file` property. If SSL is enabled, it requires entries for `keystore` and `truststore` and corresponds to the `javax.net.ssl.keyStorePassword` and `javax.net.ssl.trustStorePassword` respectively.
- `username` – If password authentication is enabled, specify the username that matches the username in the provided password file.
- `keystore_path` – If SSL is enabled, specify the full path to the Java keystore, which consists of a private key and a certificate to the public key. Corresponds to the `javax.net.ssl.keyStore` property.
- `keystore_type` – If SSL is enabled, specify the type of keystore being used. Corresponds to the `javax.net.ssl.keyStoreType` property.
- `truststore_path` – If SSL is enabled, specify the full path to the Java truststore, which must contain the remote JMX server's public certificate. Corresponds to the `javax.net.ssl.trustStore` property.
- `truststore_type` – If SSL is enabled, specify the type of truststore being used. Corresponds to the `javax.net.ssl.trustStoreType` property.
- `remote_profile` – Optional. Supported JMX remote profiles are TLS in combination with SASL profiles: `SASL/PLAIN`, `SASL/DIGEST-MD5`, and `SASL/CRAM-MD5`. Should be one of:`SASL/PLAIN`, `SASL/DIGEST-MD5`, `SASL/CRAM-MD5`, `TLS SASL/PLAIN`, `TLS SASL/DIGEST-MD5`, or `TLS SASL/CRAM-MD5`
- `realm` – Optional. The realm as required by the remote profile `SASL/DIGEST-MD5`.
- `registry_ssl_enabled` – If RMI registry authentication is enabled. Set to true if the JVM was configured with `com.sun.management.jmxremote.registry.ssl=true`.
- `insecure` Set to `true` to opt out of the validation required if the agent is configured for a non-localhost endpoint.

The following is an example of the `jmx` section of the CloudWatch agent configuration file.

```
{
```

```
  "metrics": {
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "remotehost:1314",
          "jvm": {
            "measurement": [
              "jvm.memory.heap.init",
              "jvm.memory.nonheap.used"
            ]
          },
          "kafka": {
            "measurement": [
              "kafka.request.count",
              {
                "name": "kafka.message.count",
                "rename": "KAFKA_MESSAGE_COUNT",
                "unit": "Count"
              }
            ]
          },
          "username": "cwagent",
          "keystore_path": "/path/to/keystore",
          "keystore_type": "PKCS12",
          "truststore_path": "/path/to/truststore",
          "truststore_type": "PKCS12"
        },
        {
          "endpoint": "localhost:1315",
          "kafka-producer": {
            "measurement": [
              "kafka.producer.request-rate"
            ]
          },
          "append_dimensions": {
            "service.name": "kafka/1"
          }
        }
      ]
    }
  }
}
```

Collect JVM metrics

You can use the CloudWatch agent to collect Java Virtual Machine (JVM) metrics. To set this up, add a `jvm` section inside the `jmx`section of the CloudWatch agent configuration file.

The following metrics can be collected.

Metric	Dimensions	Description
`jvm.classes.loaded`	[DEFAULT]	The total number of loaded classes. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`jvm.gc.collections.count`	[DEFAULT], `name`	The total number of garbage collections that have occurred. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`jvm.gc.collections.elapsed`	[DEFAULT], `name`	The approximate accumulated garbage

Metric	Dimensions	Description
		collection elapsed time. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`jvm.memory.heap.init`	[DEFAULT]	The initial amount of memory that the JVM requests from the operating system for the heap. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.heap.max	[DEFAULT]	The maximum amount of memory that can be used for the heap. **Unit:** Bytes **Meaningful statistics:** Maximum
jvm.memory.heap.used	[DEFAULT]	The current heap memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.heap.committed	[DEFAULT]	The amount of memory that is guaranteed to be available for the heap. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.nonheap.init	[DEFAULT]	The initial amount of memory that the JVM requests from the operating system for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.nonheap.max	[DEFAULT]	The maximum amount of memory that can be used for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
jvm.memory.nonheap.used	[DEFAULT]	The current non-heap memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.nonheap.committed	[DEFAULT]	The amount of memory that is guaranteed to be available for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.pool.init	[DEFAULT], name	The initial amount of memory that the JVM requests from the operating system for the memory pool. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.pool.max	[DEFAULT], name	The maximum amount of memory that can be used for the memory pool. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
`jvm.memory.pool.used`	[DEFAULT], `name`	The current memory pool memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`jvm.memory.pool.committed`	[DEFAULT], `name`	The amount of memory that is guaranteed to be available for the memory pool. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`jvm.threads.count`	[DEFAULT]	The current number of threads. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

The JVM metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name`, `k8s.deployment.name`, `k8s.namespace.name`, `k8s.node.name`, `k8s.pod.name`, and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.

Dimension	Description
name	For jvm.gc.collections metrics, the value is the garbage collector name. For jvm.memory.pool metrics, the value is the memory pool name.

Collect Kafka metrics

You can use the CloudWatch agent to collect Apache Kafka metrics. To set this up, add one or more of the following subsections inside the jmx section of the CloudWatch agent configuration file.

- Use a kafka section to collect Kafka broker metrics.
- Use a kafka-consumer section to collect Kafka consumer metrics.
- Use a kafka-producer section to collect Kafka producer metrics.

Kafka broker metrics

The following metrics can be collected for Kafka brokers.

Metric	Dimensions	Description
kafka.message.count	[DEFAULT]	The number of messages received by the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.count`	[DEFAULT], `type`	The number of requests received by the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.failed`	[DEFAULT], `type`	The number of requests to the Kafka broker that resulted in a failure. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.time.total`	[DEFAULT], `type`	The total time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.time.50p`	[DEFAULT], `type`	The 50th percentile time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.request.time.99p	[DEFAULT], type	The 99th percentile time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
kafka.request.time.avg	[DEFAULT], type	The average time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.network.io	[DEFAULT], state	The number of bytes received by or sent by the Kafka broker. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
kafka.purgatory.size	[DEFAULT], type	The number of requests waiting in purgatory. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.partition.count	[DEFAULT]	The number of partitions on the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.partition.offline	[DEFAULT]	The number of partitions that are offline. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.partition.under_replicated	[DEFAULT]	The number of under-replicated partitions. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.isr.operation.count	[DEFAULT], operation	The number of in-sync replica shrink and expand operations. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.max.lag	[DEFAULT]	The maximum lag in messages between follower and leader replicas. **Unit:** None **Meaningful statistics:** Maximum

Metric	Dimensions	Description
kafka.controller.active.count	[DEFAULT]	The number of active controllers on the broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.leader.election.rate	[DEFAULT]	Leader election rate. If this increases, it indicates broker failures. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.unclean.election.rate	[DEFAULT]	Unclean leader election rate. If this increases, it indicates broker failures. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.request.queue	[DEFAULT]	The size of the request queue. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.logs.flush.time.count	[DEFAULT]	The logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.logs.flush.time.median	[DEFAULT]	The 50th percentile value of the logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
kafka.logs.flush.time.99p	[DEFAULT]	The 99th percentile value of the logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

The Kafka broker metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are

Dimension	Description
	collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`type`	The request type. Possible values are `produce`, `fetch`, `fetchconsumer` , and `fetchfollower` .
`state`	The direction of network traffic. Possible values are `in` and `out`.
`operation`	The operation type for the in-sync replica. Possible values are `shrink` and `expand`.

Kafka consumer metrics

The following metrics can be collected for Kafka consumers.

Metric	Dimensions	Description
`kafka.consumer.fetch-rate`	[DEFAULT], `client-id`	The number of fetch requests

Metric	Dimensions	Description
		for all topics per second. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.records-lag-max`	[DEFAULT], `client-id`	The number of messages that the consumer lags behind the producer. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.total.bytes-consumed-rate`	[DEFAULT], `client-id`	The average number of bytes consumed for all topics per second. **Unit:** Bytes **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.consumer.total.fetch-size-avg	[DEFAULT], client-id	The number of bytes fetched per request for all topics. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
kafka.consumer.total.records-consumed-rate	[DEFAULT], client-id	The average number of records consumed for all topics per second. **Unit:** None **Meaningful statistics:** Average
kafka.consumer.bytes-consumed-rate	[DEFAULT], client-id , topic	The average number of bytes consumed per second. **Unit:** Bytes **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.consumer.fetch-size-avg`	[DEFAULT], `client-id` , `topic`	The number of bytes fetched per request. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.records-consumed-rate`	[DEFAULT], `client-id` , `topic`	The average number of records consumed per second. **Unit:** None **Meaningful statistics:** Average

The Kafka consumer metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information.

Dimension	Description
	On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`client-id`	The ID of the client.
`topic`	The Kafka topic.

Kafka producer metrics

The following metrics can be collected for Kafka producers.

Metric	Dimensions	Description
`kafka.producer.io-wait-time-ns-avg`	[DEFAULT], `client-id`	The average length of time the I/O thread spent waiting for a socket ready for reads or writes. **Unit:** None **Meaningful statistics:** Average
`kafka.producer.out`	[DEFAULT], `client-id`	The average number of

Metric	Dimensions	Description
going-byte-rate		outgoing bytes sent per second to all servers. **Unit:** Bytes **Meaningful statistics:** Average
kafka.producer.request-latency-avg	[DEFAULT], client-id	The average request latency. **Unit:** Milliseconds **Meaningful statistics:** Average
kafka.producer.request-rate	[DEFAULT], client-id	The average number of requests sent per second. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.producer.response-rate	[DEFAULT], client-id	The number of responses received per second. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.producer.byte-rate	[DEFAULT], client-id , topic	The average number of bytes sent per second for a topic. **Unit:** Bytes **Meaningful statistics:** Average
kafka.producer.compression-rate	[DEFAULT], client-id , topic	The average compression rate of record batches for a topic. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.producer.record-error-rate`	[DEFAULT], `client-id` , `topic`	The average per-second number of record sends that resulted in errors for a topic. **Unit:** None **Meaningful statistics:** Average
`kafka.producer.record-retry-rate`	[DEFAULT], `client-id` , `topic`	The average per-second number of retried record sends for a topic. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.producer.record-send-rate`	[DEFAULT], `client-id` , `topic`	The average number of records sent per second for a topic. **Unit:** None **Meaningful statistics:** Average

Kafka producer metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.

Dimension	Description
client-id	The ID of the client.
topic	The Kafka topic.

Collect Tomcat metrics

You can use the CloudWatch agent to collect Apache Tomcat metrics. To set this up, add a `tomcat` section inside the `metrics_collected` section of the CloudWatch agent configuration file.

The following metrics can be collected.

Metric	Dimensions	Description
tomcat.sessions	[DEFAULT]	The number of active sessions. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
tomcat.errors	[DEFAULT], proto_handler	The number of errors encountered. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`tomcat.processing_time`	[DEFAULT], `proto_handler`	The total processing time. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`tomcat.traffic`	[DEFAULT], `proto_handler`	The number of bytes received and sent. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`tomcat.threads`	[DEFAULT], `proto_handler`	The number of threads. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`tomcat.max_time`	[DEFAULT], `proto_handler` , `direction`	Maximum time to process a request. **Unit:** Milliseconds **Meaningful statistics:** Maximum
`tomcat.request_count`	[DEFAULT], `proto_handler`	The total requests. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Tomcat metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information.

Dimension	Description
	On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`proto_handler`	The `proto_handler` is an identifier for a connector, which is provided in the `<protocol>-<type>-<port>` format (for example, `http-nio-8080`).
`direction`	The traffic direction. Possible values are `received` and `sent`.

Collect metrics and traces with OpenTelemetry

You can collect metrics and traces from your applications or services using the CloudWatch agent with the OpenTelemetry Protocol (OTLP), which is a popular open source solution. You can use any OpenTelemetry SDK to send metrics and traces to the CloudWatch agent. For more information about the available OpenTelemetry SDKs, see OpenTelemetry Supported Language APIs & SDKs..

To collect OpenTelemetry metrics and traces, add an `otlp` section to the CloudWatch agent configuration file. The section has the following fields:

- `grpc_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry metrics or traces sent using gRPC Remote Procedure Calls. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK. If you omit this field, the default of `127.0.0.1:4317` is used.
- `http_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry metrics or traces sent over HTTP. The format is `ip:port`. This address must

match the address set for the HTTP exporter in the OpenTelemetry SDK. If you omit this field, the default of `127.0.0.1:4318` is used.

- `tls` – Optional. Specifies that the server should be configured with TLS.
  - `cert_file` – Path to the TLS certificate to use for TLS required connections.
  - `key_file` – Path to the TLS key to use for TLS required connections.

The `otlp` section can be placed in multiple sections within the CloudWatch agent configuration file depending on how and where you want to send the metrics and traces.

> **Important**
>
> Each `otlp` section requires a unique endpoint and port. For detailed information about splitting the metrics and traces endpoints, see OTLP Exporter Configuration in the OpenTelemetry SDK documentation.

To send metrics to CloudWatch or Amazon Managed Service for Prometheus, add the `otlp` section under `metrics_collected` within the `metrics` section. For more information about sending metrics to different destinations, see Manually create or edit the CloudWatch agent configuration file. The following example shows a configuration that sends metrics to CloudWatch:

> **Note**
>
> If you are running the agent in containerized environments and sending telemetry from outside the agent container's network, make sure to specify the endpoint as `0.0.0.0` instead of the default endpoint `127.0.0.1`.

```
{
  "metrics": {
    "metrics_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

To send metrics to Amazon CloudWatch Logs using the Embedded metric format (EMF), add the `otlp` section under `metrics_collected` within the `logs` section. This sends the EMF logs by default to the `/aws/cwagent` log group and a generated log stream. The metrics are extracted into the `CWAgent` namespace by default. The following example shows a configuration that sends metrics as EMF logs to CloudWatch Logs:

```
{
  "logs": {
    "metrics_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

To send traces to AWS X-Ray, add the `otlp` section under `traces_collected` within the `traces` section. The following example shows a configuration that sends traces to X-Ray:

```
{
  "traces": {
    "traces_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

Collect process metrics with the procstat plugin

The *procstat* plugin enables you to collect metrics from individual processes. The plugin is supported on Linux servers and on servers running supported version of Windows Server. This section describes how to configure the CloudWatch agent for procstat and view metrics the CloudWatch agent imports. It also lists the metrics that procstat collects.

> **Note**
>
> The `procstat` plugin is not supported for the Fargate launch type in Amazon ECS environments.

Topics

- Configure the CloudWatch agent for procstat
- Metrics collected by procstat
- Viewing process metrics imported by the CloudWatch agent

Configure the CloudWatch agent for procstat

To use the procstat plugin, add a `procstat` section in the `metrics_collected` section of the CloudWatch agent configuration file. There are three ways to specify the processes to monitor. You can use only one of these methods, but you can use that method to specify one or more processes to monitor.

- `pid_file`: Selects processes by the names of the process identification number (PID) files they create.
- `exe`: Selects the processes that have process names that match the string that you specify, using regular expression matching rules. The match is a "contains" match, meaning that if you specify `agent` as the term to match, processes with names like `cloudwatchagent` match the term. For more information, see Syntax.
- `pattern`: Selects processes by the command lines used to start the processes. All processes are selected that have command lines matching the specified string using regular expression matching rules. The entire command line is checked, including parameters and options used with the command.

  The match is a "contains" match, meaning that if you specify `-c` as the term to match, processes with parameters like `-config` match the term.

The CloudWatch agent uses only one of these methods, even if you include more than one of the above sections. If you specify more than one section, the CloudWatch agent uses the `pid_file` section if it is present. If not, it uses the `exe` section.

On Linux servers, the strings that you specify in an `exe` or `pattern` section are evaluated as regular expressions. On servers running Windows Server, these strings are evaluated as WMI queries. An example would be `pattern: "%apache%"`. For more information, see LIKE Operator.

Whichever method you use, you can include an optional `metrics_collection_interval` parameter, which specifies how often in seconds to collect those metrics. If you omit this parameter, the default value of 60 seconds is used.

In the examples in the following sections, the `procstat` section is the only section included in the `metrics_collected` section of the agent configuration file. Actual configuration files can also include other sections in `metrics_collected`. For more information, see Manually create or edit the CloudWatch agent configuration file.

Configure with pid_file

The following example `procstat` section monitors the processes that create the PID files `example1.pid` and `example2.pid`. Different metrics are collected from each process. Metrics collected from the process that creates `example2.pid` are collected every 10 seconds, and the metrics collected from the `example1.pid` process are collected every 60 seconds, the default value.

```
{
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "pid_file": "/var/run/example1.pid",
                    "measurement": [
                        "cpu_usage",
                        "memory_rss"
                    ]
                },
                {
                    "pid_file": "/var/run/example2.pid",
                    "measurement": [
                        "read_bytes",
                        "read_count",
                        "write_bytes"
                    ],
                    "metrics_collection_interval": 10
                }
            ]
```

```
        }
    }
}
```

Configuring with exe

The following example `procstat` section monitors all processes with names that match the strings `agent` or `plugin`. The same metrics are collected from each process.

```
{
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "exe": "agent",
                    "measurement": [
                        "cpu_time",
                        "cpu_time_system",
                        "cpu_time_user"
                    ]
                },
                {
                    "exe": "plugin",
                    "measurement": [
                        "cpu_time",
                        "cpu_time_system",
                        "cpu_time_user"
                    ]
                }
            ]
        }
    }
}
```

Configuring with pattern

The following example `procstat` section monitors all processes with command lines that match the strings `config` or `-c`. The same metrics are collected from each process.

```
{
    "metrics": {
        "metrics_collected": {
```

```
            "procstat": [
                {
                    "pattern": "config",
                    "measurement": [
                        "rlimit_memory_data_hard",
                        "rlimit_memory_data_soft",
                        "rlimit_memory_stack_hard",
                        "rlimit_memory_stack_soft"
                    ]
                },
                {
                    "pattern": "-c",
                    "measurement": [
                        "rlimit_memory_data_hard",
                        "rlimit_memory_data_soft",
                        "rlimit_memory_stack_hard",
                        "rlimit_memory_stack_soft"
                    ]
                }
            ]
        }
    }
}
```

Metrics collected by procstat

The following table lists the metrics that you can collect with the `procstat` plugin.

The CloudWatch agent adds `procstat` to the beginning of the following metric names. There is a different syntax depending on whether it was collected from a Linux server or a server running Windows Server. For example, the `cpu_time` metric appears as `procstat_cpu_time` when collected from Linux and as `procstat cpu_time` when collected from Windows Server.

Metric name	Available on	Description
`cpu_time`	Linux	The amount of time that the process uses the CPU. This metric is measured in

Metric name	Available on	Description
		hundredths of a second. Unit: Count
cpu_time_guest	Linux	The amount of time that the process is in guest mode. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_guest_nice	Linux	The amount of time that the process is running in a nice guest. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_idle	Linux	The amount of time that the process is in idle mode. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_iowait	Linux	The amount of time that the process is waiting for I/O operations to complete. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_irq	Linux	The amount of time that the process is servicing interrupts. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_nice	Linux	The amount of time that the process is in nice mode. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_soft_irq	Linux	The amount of time that the process is servicing software interrupts. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_steal	Linux	The amount of time spent running in other operating systems when running in a virtualized environment. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_stolen	Linux, Windows Server	The amount of time that the process is in *stolen time*, which is time spent in other operating systems in a virtualized environment. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_system	Linux, Windows Server, macOS	The amount of time that the process is in system mode. This metric is measured in hundredths of a second. Type: Float Unit: Count

Metric name	Available on	Description
cpu_time_user	Linux, Windows Server, macOS	The amount of time that the process is in user mode. This metric is measured in hundredths of a second. Unit: Count
cpu_usage	Linux, Windows Server, macOS	The percentage of time that the process is active in any capacity. Unit: Percent
memory_data	Linux, macOS	The amount of memory that the process uses for data. Unit: Bytes
memory_locked	Linux, macOS	The amount of memory that the process has locked. Unit: Bytes

Metric name	Available on	Description
memory_rss	Linux, Windows Server, macOS	The amount of real memory (resident set) that the process is using. Unit: Bytes
memory_stack	Linux, macOS	The amount of stack memory that the process is using. Unit: Bytes
memory_swap	Linux, macOS	The amount of swap memory that the process is using. Unit: Bytes
memory_vms	Linux, Windows Server, macOS	The amount of virtual memory that the process is using. Unit: Bytes

Metric name	Available on	Description
num_fds	Linux	The number of file descriptors that this process has open. Unit: None
num_threads	Linux, Windows, macOS	The number of threads in this process. Unit: None
pid	Linux, Windows Server, macOS	Process identifier (ID). Unit: None

Metric name	Available on	Description
`pid_count`	Linux, Windows Server. macOS	The number of process IDs associated with the process. On Linux servers and macOS computers the full name of this metric is `procstat_lookup_pid_count` and on Windows Server it is `procstat_lookup pid_count` . Unit: None
`read_bytes`	Linux, Windows Server	The number of bytes that the process has read from disks. Unit: Bytes

Metric name	Available on	Description
write_bytes	Linux, Windows Server	The number of bytes that the process has written to disks. Unit: Bytes
read_count	Linux, Windows Server	The number of disk read operations that the process has executed. Unit: None
rlimit_realtime_priority_hard	Linux	The hard limit on the real-time priority that can be set for this process. Unit: None
rlimit_realtime_priority_soft	Linux	The soft limit on the real-time priority that can be set for this process. Unit: None

Metric name	Available on	Description
rlimit_signals_pending_hard	Linux	The hard limit on maximum number of signals that can be queued by this process. Unit: None
rlimit_signals_pending_soft	Linux	The soft limit on maximum number of signals that can be queued by this process. Unit: None
rlimit_nice_priority_hard	Linux	The hard limit on the maximum nice priority that can be set by this process. Unit: None

Metric name	Available on	Description
rlimit_nice_priority_soft	Linux	The soft limit on the maximum nice priority that can be set by this process. Unit: None
rlimit_num_fds_hard	Linux	The hard limit on the maximum number of file descriptors that this process can have open. Unit: None
rlimit_num_fds_soft	Linux	The soft limit on the maximum number of file descriptors that this process can have open. Unit: None

Metric name	Available on	Description
write_count	Linux, Windows Server	The number of disk write operations that the process has executed. Unit: None
involuntary_context_switches	Linux	The number of times that the process was involuntarily context-switched. Unit: None
voluntary_context_switches	Linux	The number of times that the process was context-switched voluntarily. Unit: None
realtime_priority	Linux	The current usage of real-time priority for the process. Unit: None

Metric name	Available on	Description
nice_priority	Linux	The current usage of nice priority for the process. Unit: None
signals_pending	Linux	The number of signals pending to be handled by the process. Unit: None
rlimit_cpu_time_hard	Linux	The hard CPU time resource limit for the process. Unit: None
rlimit_cpu_time_soft	Linux	The soft CPU time resource limit for the process. Unit: None
rlimit_file_locks_hard	Linux	The hard file locks resource limit for the process. Unit: None

Metric name	Available on	Description
rlimit_file_locks_soft	Linux	The soft file locks resource limit for the process. Unit: None
rlimit_memory_data_hard	Linux	The hard resource limit on the process for memory used for data. Unit: Bytes
rlimit_memory_data_soft	Linux	The soft resource limit on the process for memory used for data. Unit: Bytes
rlimit_memory_locked_hard	Linux	The hard resource limit on the process for locked memory. Unit: Bytes

Metric name	Available on	Description
rlimit_memory_locked_soft	Linux	The soft resource limit on the process for locked memory. Unit: Bytes
rlimit_memory_rss_hard	Linux	The hard resource limit on the process for physical memory. Unit: Bytes
rlimit_memory_rss_soft	Linux	The soft resource limit on the process for physical memory. Unit: Bytes
rlimit_memory_stack_hard	Linux	The hard resource limit on the process stack. Unit: Bytes
rlimit_memory_stack_soft	Linux	The soft resource limit on the process stack. Unit: Bytes

Metric name	Available on	Description
rlimit_memory_vms_hard	Linux	The hard resource limit on the process for virtual memory. Unit: Bytes
rlimit_memory_vms_soft	Linux	The soft resource limit on the process for virtual memory. Unit: Bytes

Viewing process metrics imported by the CloudWatch agent

After importing process metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view process metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view process metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

b. To sort the table, use the column heading.

c. To filter by resource, choose the resource ID and then choose **Add to search**.

d. To filter by metric, choose the metric name and then choose **Add to search**.

6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Retrieve custom metrics with StatsD

You can retrieve additional custom metrics from your applications or services using the CloudWatch agent with the `StatsD` protocol. StatsD is a popular open-source solution that can gather metrics from a wide variety of applications. StatsD is especially useful for instrumenting your own metrics. For an example of using the CloudWatch agent and StatsD together, see How to better monitor your custom application metrics using Amazon CloudWatch Agent.

`StatsD` is supported on both Linux servers and servers running Windows Server. CloudWatch supports the following `StatsD` format:

```
MetricName:value|type|@sample_rate|#tag1:
  value,tag1...
```

- `MetricName` – A string with no colons, bars, # characters, or @ characters.
- `value` – This can be either integer or float.
- `type` – Specify `c` for counter, `g` for gauge, `ms` for timer, `h` for histogram, or `s` for set.
- `sample_rate` – (Optional) A float between 0 and 1, inclusive. Use only for counter, histogram, and timer metrics. The default value is 1 (sampling 100% of the time).
- `tags` – (Optional) A comma-separated list of tags. `StatsD` tags are similar to dimensions in CloudWatch. Use colons for key/value tags, such as `env:prod`.

You can use any `StatsD` client that follows this format to send the metrics to the CloudWatch agent. For more information about some of the available `StatsD` clients, see the StatsD client page on GitHub.

To collect these custom metrics, add a `"statsd": {}` line to the `metrics_collected` section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it's done for you. For more information, see Create the CloudWatch agent configuration file.

The `StatsD` default configuration works for most users. There are optional fields that you can add to the **statsd** section of the agent configuration file as needed:

- `service_address` – The service address to which the CloudWatch agent should listen. The format is *`ip`*`:`*`port`*. If you omit the IP address, the agent listens on all available interfaces. Only the UDP format is supported, so you don't need to specify a UDP prefix.

  The default value is `:8125`.
- `metrics_collection_interval` – How often in seconds that the `StatsD` plugin runs and collects metrics. The default value is 10 seconds. The range is 1–172,000.
- `metrics_aggregation_interval` – How often in seconds CloudWatch aggregates metrics into single data points. The default value is 60 seconds.

  For example, if `metrics_collection_interval` is 10 and `metrics_aggregation_interval` is 60, CloudWatch collects data every 10 seconds. After each minute, the six data readings from that minute are aggregated into a single data point, which is sent to CloudWatch.

  The range is 0–172,000. Setting `metrics_aggregation_interval` to 0 disables the aggregation of `StatsD` metrics.
- `allowed_pending_messages` – The number of UDP messages that are allowed to queue up. When the queue is full, the StatsD server starts dropping packets. The default value is 10000.
- `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

The following is an example of the **statsd** section of the agent configuration file, using the default port and custom collection and aggregation intervals.

```
{
   "metrics":{
      "metrics_collected":{
         "statsd":{
```

```
            "service_address":":8125",
            "metrics_collection_interval":60,
            "metrics_aggregation_interval":300
         }
      }
   }
}
```

Viewing StatsD metrics imported by the CloudWatch agent

After importing StatsD metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view StatsD metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view StatsD metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:

   a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

   b. To sort the table, use the column heading.

   c. To filter by resource, choose the resource ID and then choose **Add to search**.

   d. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Retrieve custom metrics with collectd

You can retrieve additional metrics from your applications or services using the CloudWatch agent with the collectd protocol, which is supported only on Linux servers. collectd is a popular open-source solution with plugins that can gather system statistics for a wide variety of applications. By

combining the system metrics that the CloudWatch agent can already collect with the additional metrics from collectd, you can better monitor, analyze, and troubleshoot your systems and applications. For more information about collectd, see collectd - The system statistics collection daemon.

You use the collectd software to send the metrics to the CloudWatch agent. For the collectd metrics, the CloudWatch agent acts as the server while the collectd plugin acts as the client.

The collectd software is not installed automatically on every server. On a server running Amazon Linux 2, follow these steps to install collectd

```
sudo amazon-linux-extras install collectd
```

For information about installing collectd on other systems, see the Download page for collectd.

To collect these custom metrics, add a **"collectd": {}** line to the **metrics_collected** section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it is done for you. For more information, see Create the CloudWatch agent configuration file.

Optional parameters are also available. If you are using collectd and you do not use `/etc/collectd/auth_file` as your **collectd_auth_file**, you must set some of these options.

- **service_address:** The service address to which the CloudWatch agent should listen. The format is "udp://*ip*:*port*. The default is udp://127.0.0.1:25826.
- **name_prefix:** A prefix to attach to the beginning of the name of each collectd metric. The default is `collectd_`. The maximum length is 255 characters.
- **collectd_security_level:** Sets the security level for network communication. The default is **encrypt**.

  encrypt specifies that only encrypted data is accepted. **sign** specifies that only signed and encrypted data is accepted. **none** specifies that all data is accepted. If you specify a value for **collectd_auth_file**, encrypted data is decrypted if possible.

  For more information, see Client setup and Possible interactions in the collectd Wiki.
- **collectd_auth_file** Sets a file in which user names are mapped to passwords. These passwords are used to verify signatures and to decrypt encrypted network packets. If given, signed data is verified and encrypted packets are decrypted. Otherwise, signed data is accepted without checking the signature and encrypted data cannot be decrypted.

The default is `/etc/collectd/auth_file`.

If **collectd_security_level** is set to **none**, this is optional. If you set **collectd_security_level** to `encrypt` or **sign**, you must specify **collectd_auth_file**.

For the format of the auth file, each line is a user name followed by a colon and any number of spaces followed by the password. For example:

```
user1: user1_password

user2: user2_password
```

- **collectd_typesdb:** A list of one or more files that contain the dataset descriptions. The list must be surrounded by brackets, even if there is just one entry in the list. Each entry in the list must be surrounded by double quotes. If there are multiple entries, separate them with commas. The default on Linux servers is `["/usr/share/collectd/types.db"]`. The default on macOs computers depends on the version of collectd. For example, `["/usr/local/Cellar/collectd/5.12.0/share/collectd/types.db"]`.

  For more information, see https://www.collectd.org/documentation/manpages/types.db.html.
- **metrics_aggregation_interval:** How often in seconds CloudWatch aggregates metrics into single data points. The default is 60 seconds. The range is 0 to 172,000. Setting it to 0 disables the aggregation of collectd metrics.

The following is an example of the collectd section of the agent configuration file.

```
{
   "metrics":{
      "metrics_collected":{
         "collectd":{
            "name_prefix":"My_collectd_metrics_",
            "metrics_aggregation_interval":120
         }
      }
   }
}
```

Viewing collected metrics imported by the CloudWatch agent

After importing collectd metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view collectd metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view collectd metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:
    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
    b. To sort the table, use the column heading.
    c. To filter by resource, choose the resource ID and then choose **Add to search**.
    d. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Set up and configure Prometheus metrics collection on Amazon EC2 instances

The following sections explain how to install the CloudWatch agent with Prometheus monitoring on EC2 instances, and how to configure the agent to scrape additional targets. It also provides tutorials for setting up sample workloads to use testing with Prometheus monitoring.

Both Linux and Windows instances are supported.

For information about the operating systems supported by the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent

VPC security group requirements

If you are using a VPC, the following requirements apply.

- The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.
- The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

- Step 1: Install the CloudWatch agent
- Step 2: Scrape Prometheus sources and import metrics
- Example: Set up Java/JMX sample workloads for Prometheus metric testing

Step 1: Install the CloudWatch agent

The first step is to install the CloudWatch agent on the EC2 instance. For instructions, see Installing the CloudWatch agent.

Step 2: Scrape Prometheus sources and import metrics

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. One is for the standard Prometheus configurations as documented in <scrape_config>in the Prometheus documentation. The other is for the CloudWatch agent configuration.

Prometheus scrape configuration

The CloudWatch agent supports the standard Prometheus scrape configurations as documented in <scrape_config> in the Prometheus documentation. You can edit this section to update the configurations that are already in this file, and add additional Prometheus scraping targets. A sample configuration file contains the following global configuration lines:

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
- job_name: MY_JOB
  sample_limit: 10000
  file_sd_configs:
```

```
    - files: ["C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus_sd_1.yaml",
"C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus_sd_2.yaml"]
```

The `global` section specifies parameters that are valid in all configuration contexts. They also serve as defaults for other configuration sections. It contains the following parameters:

- `scrape_interval`— Defines how frequently to scrape targets.
- `scrape_timeout`— Defines how long to wait before a scrape request times out.

The `scrape_configs` section specifies a set of targets and parameters that define how to scrape them. It contains the following parameters:

- `job_name`— The job name assigned to scraped metrics by default.
- `sample_limit`— Per-scrape limit on the number of scraped samples that will be accepted.
- `file_sd_configs`— List of file service discovery configurations. It reads a set of files containing a list of zero or more static configs. The `file_sd_configs` section contains a `files` parameter which defines patterns for files from which target groups are extracted.

The CloudWatch agent supports the following service discovery configuration types.

`static_config` Allows specifying a list of targets and a common label set for them. It is the canonical way to specify static targets in a scrape configuration.

The following is a sample static config to scrape Prometheus metrics from a local host. Metrics can also be scraped from other servers if the Prometheus port is open to the server where the agent runs.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_sd_1.yaml
- targets:
    - 127.0.0.1:9404
  labels:
    key1: value1
    key2: value2
```

This example contains the following parameters:

- `targets`— The targets scraped by the static config.
- `labels`— Labels assigned to all metrics that are scraped from the targets.

`ec2_sd_config` Allows retrieving scrape targets from Amazon EC2 instances. The following is a sample `ec2_sd_config` to scrape Prometheus metrics from a list of EC2 instances. The Prometheus ports of these instances have to open to the server where the CloudWatch agent runs. The IAM role for the EC2 instance where the CloudWatch agent runs must include the `ec2:DescribeInstance` permission. For example, you could attach the managed policy **AmazonEC2ReadOnlyAccess** to the instance running the CloudWatch agent.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: MY_JOB
    sample_limit: 10000
    ec2_sd_configs:
      - region: us-east-1
        port: 9404
        filters:
          - name: instance-id
            values:
              - i-98765432109876543
              - i-12345678901234567
```

This example contains the following parameters:

- `region`— The AWS Region where the target EC2 instance is. If you leave this blank, the Region from the instance metadata is used.
- `port`— The port to scrape metrics from.
- `filters`— Optional filters to use to filter the instance list. This example filters based on EC2 instance IDs. For more criteria that you can filter on, see DescribeInstances.

CloudWatch agent configuration for Prometheus

The CloudWatch agent configuration file includes `prometheus` sections under both `logs` and `metrics_collected`. It includes the following parameters.

- **cluster_name**— specifies the cluster name to be added as a label in the log event. This field is optional.
- **log_group_name**— specifies the log group name for the scraped Prometheus metrics.

- **prometheus_config_path**— specifies the Prometheus scrape configuration file path.
- **emf_processor**— specifies the embedded metric format processor configuration. For more information about embedded metric format, see Embedding metrics within logs.

  The `emf_processor` section can contain the following parameters:

  - **metric_declaration_dedup**— It set to true, the de-duplication function for the embedded metric format metrics is enabled.
  - **metric_namespace**— Specifies the metric namespace for the emitted CloudWatch metrics.
  - **metric_unit**— Specifies the metric name:metric unit map. For information about supported metric units, see MetricDatum.
  - **metric_declaration**— are sections that specify the array of logs with embedded metric format to be generated. There are `metric_declaration` sections for each Prometheus source that the CloudWatch agent imports from by default. These sections each include the following fields:
    - `source_labels` specifies the value of the labels that are checked by the `label_matcher` line.
    - `label_matcher` is a regular expression that checks the value of the labels listed in `source_labels`. The metrics that match are enabled for inclusion in the embedded metric format sent to CloudWatch.
    - `metric_selectors` is a regular expression that specifies the metrics to be collected and sent to CloudWatch.
    - `dimensions` is the list of labels to be used as CloudWatch dimensions for each selected metric.

The following is an example CloudWatch agent configuration for Prometheus.

```
{
   "logs":{
      "metrics_collected":{
         "prometheus":{
            "cluster_name":"prometheus-cluster",
            "log_group_name":"Prometheus",
            "prometheus_config_path":"C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\prometheus.yaml",
            "emf_processor":{
               "metric_declaration_dedup":true,
               "metric_namespace":"CWAgent-Prometheus",
```

```
                "metric_unit":{
                   "jvm_threads_current": "Count",
                   "jvm_gc_collection_seconds_sum": "Milliseconds"
                },
                "metric_declaration":[
                   {
                      "source_labels":[
                         "job", "key2"
                      ],
                      "label_matcher":"MY_JOB;^value2",
                      "dimensions":[
                         [
                            "key1", "key2"
                         ],
                         [
                            "key2"
                         ]
                      ],
                      "metric_selectors":[
                         "^jvm_threads_current$",
                         "^jvm_gc_collection_seconds_sum$"
                      ]
                   }
                ]
             }
          }
       }
    }
}
```

The previous example configures an embedded metric format section to be sent as a log event if the following conditions are met:

- The value of the label `job` is `MY_JOB`
- The value of the label `key2` is `value2`
- The Prometheus metrics `jvm_threads_current` and `jvm_gc_collection_seconds_sum` contains both `job` and `key2` labels.

The log event that is sent includes the following highlighted section.

```
{
```

```
    "CloudWatchMetrics": [
        {
            "Metrics": [
                {
                    "Unit": "Count",
                    "Name": "jvm_threads_current"
                },
                {
                    "Unit": "Milliseconds",
                    "Name": "jvm_gc_collection_seconds_sum"
                }
            ],
            "Dimensions": [
                [
                    "key1",
                    "key2"
                ],
                [
                    "key2"
                ]
            ],
            "Namespace": "CWAgent-Prometheus"
        }
    ],
    "ClusterName": "prometheus-cluster",
    "InstanceId": "i-0e45bd06f196096c8",
    "Timestamp": "1607966368109",
    "Version": "0",
    "host": "EC2AMAZ-PDDOIUM",

```

Example: Set up Java/JMX sample workloads for Prometheus metric testing

JMX Exporter is an official Prometheus exporter that can scrape and expose JMX mBeans as Prometheus metrics. For more information, see prometheus/jmx_exporter.

The CloudWatch agent can collect predefined Prometheus metrics from Java Virtual Machine (JVM), Hjava, and Tomcat (Catalina), from a JMX exporter on EC2 instances.

Step 1: Install the CloudWatch agent

The first step is to install the CloudWatch agent on the EC2 instance. For instructions, see Installing the CloudWatch agent.

Step 2: Start the Java/JMX workload

The next step is to start the Java/JMX workload.

First, download the latest JMX exporter jar file from the following location: prometheus/jmx_exporter.

Use the jar for your sample application

The example commands in the following sections use `SampleJavaApplication-1.0-SNAPSHOT.jar` as the jar file. Replace these parts of the commands with the jar for your application.

Prepare the JMX exporter configuration

The `config.yaml` file is the JMX exporter configuration file. For more information, see Configuration in the JMX exporter documentation.

Here is a sample configuration for Java and Tomcat.

```
---
lowercaseOutputName: true
lowercaseOutputLabelNames: true

rules:
- pattern: 'java.lang<type=OperatingSystem><>(FreePhysicalMemorySize|
TotalPhysicalMemorySize|FreeSwapSpaceSize|TotalSwapSpaceSize|SystemCpuLoad|
ProcessCpuLoad|OpenFileDescriptorCount|AvailableProcessors)'

  name: catalina_session_$3_total
  labels:
    context: "$2"
    host: "$1"
  help: Catalina session $3 total
  type: COUNTER

- pattern: ".*"
```

Start the Java application with the Prometheus exporter

Start the sample application. This will emit Prometheus metrics to port 9404. Be sure to replace the entry point `com.gubupt.sample.app.App` with the correct information for your sample java application.

On Linux, enter the following command.

```
$ nohup java -javaagent:./jmx_prometheus_javaagent-0.14.0.jar=9404:./config.yaml -cp
  ./SampleJavaApplication-1.0-SNAPSHOT.jar com.gubupt.sample.app.App &
```

On Windows, enter the following command.

```
PS C:\> java -javaagent:.\jmx_prometheus_javaagent-0.14.0.jar=9404:.\config.yaml -cp  .
\SampleJavaApplication-1.0-SNAPSHOT.jar com.gubupt.sample.app.App
```

Verify the Prometheus metrics emission

Verify that Prometheus metrics are being emitted.

On Linux, enter the following command.

```
$ curl localhost:9404
```

On Windows, enter the following command.

```
PS C:\> curl  http://localhost:9404
```

Sample output on Linux:

```
StatusCode        : 200
StatusDescription : OK
Content           : # HELP jvm_classes_loaded The number of classes that are currently
 loaded in the JVM

ParsedHtml        : System.__ComObject
RawContentLength  : 71908
```

Step 3: Configure the CloudWatch agent to scrape Prometheus metrics

Next, set up the Prometheus scrape configuration in the CloudWatch agent configuration file.

To set up the Prometheus scrape configuration for the Java/JMX example

1. Set up the configuration for `file_sd_config` and `static_config`.

   On Linux, enter the following command.

   ```
   $ cat /opt/aws/amazon-cloudwatch-agent/var/prometheus.yaml
   global:
     scrape_interval: 1m
     scrape_timeout: 10s
   scrape_configs:
     - job_name: jmx
       sample_limit: 10000
       file_sd_configs:
         - files: [ "/opt/aws/amazon-cloudwatch-agent/var/prometheus_file_sd.yaml" ]
   ```

   On Windows, enter the following command.

   ```
   PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
   global:
     scrape_interval: 1m
     scrape_timeout: 10s
   scrape_configs:
     - job_name: jmx
       sample_limit: 10000
       file_sd_configs:
         - files: [ "C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
   \prometheus_file_sd.yaml" ]
   ```

2. Set up the scrape targets configuration.

   On Linux, enter the following command.

   ```
   $ cat /opt/aws/amazon-cloudwatch-agent/var/prometheus_file_sd.yaml
   ```

```
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
    os: linux
```

On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_file_sd.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
    os: windows
```

3. Set up the Prometheus scrape configuration by `ec2_sc_config`. Replace *your-ec2-instance-id* with the correct EC2 instance ID.

   On Linux, enter the following command.

```
$ cat .\prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: jmx
    sample_limit: 10000
    ec2_sd_configs:
      - region: us-east-1
        port: 9404
        filters:
          - name: instance-id
            values:
              - your-ec2-instance-id
```

   On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_file_sd.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
```

```
    os: windows
```

4. Set up the CloudWatch agent configuration. First, navigate to the correct directory. On Linux, it is `/opt/aws/amazon-cloudwatch-agent/var/cwagent-config.json`. On Windows, it is `C:\ProgramData\Amazon\AmazonCloudWatchAgent\cwagent-config.json`.

   The following is a sample configuration with Java/JHX Prometheus metrics defined. Be sure to replace *`path-to-Prometheus-Scrape-Configuration-file`* with the correct path.

```
{
  "agent": {
    "region": "us-east-1"
  },
  "logs": {
    "metrics_collected": {
      "prometheus": {
        "cluster_name": "my-cluster",
        "log_group_name": "prometheus-test",
        "prometheus_config_path": "path-to-Prometheus-Scrape-Configuration-file",
        "emf_processor": {
          "metric_declaration_dedup": true,
          "metric_namespace": "PrometheusTest",
          "metric_unit":{
            "jvm_threads_current": "Count",
            "jvm_classes_loaded": "Count",
            "java_lang_operatingsystem_freephysicalmemorysize": "Bytes",
            "catalina_manager_activesessions": "Count",
            "jvm_gc_collection_seconds_sum": "Seconds",
            "catalina_globalrequestprocessor_bytesreceived": "Bytes",
            "jvm_memory_bytes_used": "Bytes",
            "jvm_memory_pool_bytes_used": "Bytes"
          },
          "metric_declaration": [
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["instance"]],
              "metric_selectors": [
                "^jvm_threads_current$",
                "^jvm_classes_loaded$",
                "^java_lang_operatingsystem_freephysicalmemorysize$",
                "^catalina_manager_activesessions$",
                "^jvm_gc_collection_seconds_sum$",
```

```
                "^catalina_globalrequestprocessor_bytesreceived$"
              ]
            },
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["area"]],
              "metric_selectors": [
                "^jvm_memory_bytes_used$"
              ]
            },
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["pool"]],
              "metric_selectors": [
                "^jvm_memory_pool_bytes_used$"
              ]
            }
          ]
        }
      }
    },
    "force_flush_interval": 5
  }
}
```

5. Restart the CloudWatch agent by entering one of the following commands.

   On Linux, enter the following command.

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m ec2 -s -c file:/opt/aws/amazon-cloudwatch-agent/var/cwagent-config.json
   ```

   On Windows, enter the following command.

   ```
   & "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
    -a fetch-config -m ec2 -s -c file:C:\ProgramData\Amazon\AmazonCloudWatchAgent
   \cwagent-config.json
   ```

Viewing the Prometheus metrics and logs

You can now view the Java/JMX metrics being collected.

To view the metrics for your sample Java/JMX workload

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the Region where your cluster is running, choose **Metrics** in the left navigation pane. Find the **PrometheusTest** namespace to see the metrics.
3. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group **prometheus-test**.

Configure CloudWatch agent service and environment names for related entities

The CloudWatch agent can send metrics and logs with entity data to support the Explore related pane in the CloudWatch console. The service name or environment name can be configured by the CloudWatch Agent JSON configuration.

> **Note**
>
> The agent configuration may be overridden. For details about how the agent decides what data to send for related entities, see Using the CloudWatch agent with related telemetry.

For metrics, it can be configured at the agent, metrics, or plugin level. For logs it can be configured at the agent, logs, or file level. The most specific configuration is always used. For example if the configuration exists at the agent level and metrics level, then metrics will use the metric configuration, and anything else (logs) will use the agent configuration. The following example shows different ways to configure the service name and environment name.

```
{
  "agent": {
    "service.name": "agent-level-service",
    "deployment.environment": "agent-level-environment"
  },

  "metrics": {
    "service.name": "metric-level-service",
     "deployment.environment": "metric-level-environment",
```

```
    "metrics_collected": {
      "statsd": {
        "service.name": "statsd-level-service",
        "deployment.environment": "statsd-level-environment",
      },
      "collectd": {
        "service.name": "collectdd-level-service",
        "deployment.environment": "collectd-level-environment",
      }
    }

  },

  "logs": {
    "service.name": "log-level-service",
    "deployment.environment": "log-level-environment",

    "logs_collected": {
      "files": {
        "collect_list": [
          {
            "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
            "log_group_name": "amazon-cloudwatch-agent.log",
            "log_stream_name": "amazon-cloudwatch-agent.log",

            "service.name": "file-level-service",
            "deployment.environment": "file-level-environment"
          }
        ]
      }
    }

  }
}
```

Starting the CloudWatch agent

You can start the CloudWatch agent using either Systems Manager Run Command or the command line.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

Start the CloudWatch agent using the command line on Amazon EC2

Follow these steps to use the command line to start the CloudWatch agent on on Amazon EC2.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

To use the command line to start the CloudWatch agent on on Amazon EC2

1. Copy the agent configuration file that you want to use to the server where you're going to run the agent. Note the pathname where you copy it to.
2. In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

   Enter one of the following commands. Replace *`configuration-file-path`* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

   On an EC2 instance running Linux, enter the following command.

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m ec2 -s -c file:configuration-file-path
   ```

   On an on-premises server running Linux, enter the following:

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m onPremise -s -c file:configuration-file-path
   ```

   On an EC2 instance running Windows Server, enter the following from the PowerShell console:

   ```
   & "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
   a fetch-config -m ec2 -s -c file:configuration-file-path
   ```

   On an on-premises server running Windows Server, enter the following from the PowerShell console:

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m onPremise -s -c file:configuration-file-path
```

Start the CloudWatch agent on an on-premises server

Follow these steps to start the CloudWatch agent on an on-premises server.

To use SSM Agent to start the CloudWatch agent on an on-premises server

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, select the instance where you installed the agent.
6. In the **Action** list, choose **configure**.
7. In the **Mode** list, choose **onPremise**.
8. In the **Optional Configuration Location** box, enter the name of the agent configuration file that you created with the wizard and stored in the Parameter Store.
9. Choose **Run**.

   The agent starts with the configuration you specified in the configuration file.

To use the command line to start the CloudWatch agent on an on-premises server

- In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

  Linux: If you saved the configuration file in the Systems Manager Parameter Store, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m onPremise -s -c ssm:configuration-parameter-store-name
```

Linux: If you saved the configuration file on the local computer, enter the following command. Replace *configuration-file-path* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m onPremise -s -c file:configuration-file-path
```

Windows Server: If you saved the agent configuration file in Systems Manager Parameter Store, enter the following from the PowerShell console:

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m onPremise -s -c ssm:configuration-parameter-store-name
```

Windows Server: If you saved the agent configuration file on the local computer, enter the following from the PowerShell console. Replace *configuration-file-path* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m onPremise -s -c file:configuration-file-path
```

Metrics collected by the CloudWatch agent

You can collect metrics from servers by installing the CloudWatch agent on the server. You can install the agent on both Amazon EC2 instances and on-premises servers. You can also install the agent on computers running Linux, Windows Server, or macOS. If you install the agent on an Amazon EC2 instance, the metrics the agent collects are in addition to the metrics enabled by default on Amazon EC2 instances. For information about installing the CloudWatch agent on an instance, see Collect metrics, logs, and traces using the CloudWatch agent. You can use this section to learn about metrics the CloudWatch agent collects.

Metrics collected by the CloudWatch agent on Windows Server instances

On a server running Windows Server, installing the CloudWatch agent enables you to collect the metrics associated with the counters in Windows Performance Monitor. The CloudWatch metric names for these counters are created by putting a space between the object name and the counter name. For example, the `% Interrupt Time` counter of the `Processor` object is given the metric name `Processor % Interrupt Time` in CloudWatch. For more information about Windows Performance Monitor counters, see the Microsoft Windows Server documentation.

The default namespace for metrics collected by the CloudWatch agent is `CWAgent`, although you can specify a different namespace when you configure the agent.

Metrics collected by the CloudWatch agent on Linux and macOS instances

The following table lists the metrics that you can collect with the CloudWatch agent on Linux servers and macOS computers.

Metric	Description
`cpu_time_active`	The amount of time that the CPU is active in any capacity. This metric is measured in hundredths of a second. Unit: None
`cpu_time_guest`	The amount of time that the CPU is running a virtual CPU for a guest operating system. This metric is measured in hundredths of a second. Unit: None
`cpu_time_guest_nice`	The amount of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. This metric is measured in hundredths of a second.

Metric	Description
	Unit: None
cpu_time_idle	The amount of time that the CPU is idle. This metric is measured in hundredths of a second. Unit: None
cpu_time_iowait	The amount of time that the CPU is waiting for I/O operations to complete. This metric is measured in hundredths of a second. Unit: None
cpu_time_irq	The amount of time that the CPU is servicing interrupts. This metric is measured in hundredths of a second. Unit: None
cpu_time_nice	The amount of time that the CPU is in user mode with low-priority processes, which can easily be interrupted by higher-priority processes. This metric is measured in hundredths of a second. Unit: None
cpu_time_softirq	The amount of time that the CPU is servicing software interrupts. This metric is measured in hundredths of a second. Unit: None
cpu_time_steal	The amount of time that the CPU is in *stolen time*, which is time spent in other operating systems in a virtualized environment. This metric is measured in hundredths of a second. Unit: None

Metric	Description
cpu_time_system	The amount of time that the CPU is in system mode. This metric is measured in hundredths of a second. Unit: None
cpu_time_user	The amount of time that the CPU is in user mode. This metric is measured in hundredths of a second. Unit: None
cpu_usage_active	The percentage of time that the CPU is active in any capacity. Unit: Percent
cpu_usage_guest	The percentage of time that the CPU is running a virtual CPU for a guest operating system. Unit: Percent
cpu_usage_guest_nice	The percentage of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. Unit: Percent
cpu_usage_idle	The percentage of time that the CPU is idle. Unit: Percent
cpu_usage_iowait	The percentage of time that the CPU is waiting for I/O operations to complete. Unit: Percent

Metric	Description
cpu_usage_irq	The percentage of time that the CPU is servicing interrupts. Unit: Percent
cpu_usage_nice	The percentage of time that the CPU is in user mode with low-priority processes, which higher-priority processes can easily interrupt. Unit: Percent
cpu_usage_softirq	The percentage of time that the CPU is servicing software interrupts. Unit: Percent
cpu_usage_steal	The percentage of time that the CPU is in *stolen time*, or time spent in other operating systems in a virtualized environment. Unit: Percent
cpu_usage_system	The percentage of time that the CPU is in system mode. Unit: Percent
cpu_usage_user	The percentage of time that the CPU is in user mode. Unit: Percent
disk_free	Free space on the disks. Unit: Bytes
disk_inodes_free	The number of available index nodes on the disk. Unit: Count

Metric	Description
`disk_inodes_total`	The total number of index nodes reserved on the disk. Unit: Count
`disk_inodes_used`	The number of used index nodes on the disk. Unit: Count
`disk_total`	Total space on the disks, including used and free. Unit: Bytes
`disk_used`	Used space on the disks. Unit: Bytes
`disk_used_percent`	The percentage of total disk space that is used. Unit: Percent
`diskio_iops_in_progress`	The number of I/O requests that have been issued to the device driver but have not yet completed. Unit: Count
`diskio_io_time`	The amount of time that the disk has had I/O requests queued. Unit: Milliseconds The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`diskio_reads`	The number of disk read operations. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.

Metric	Description
diskio_read_bytes	The number of bytes read from the disks. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_read_time	The amount of time that read requests have waited on the disks. Multiple read requests waiting at the same time increase the number. For example, if 5 requests all wait for an average of 100 milliseconds, 500 is reported. Unit: Milliseconds The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_writes	The number disk write operations. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_write_bytes	The number of bytes written to the disks. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
diskio_write_time	The amount of time that write requests have waited on the disks. Multiple write requests waiting at the same time increase the number. For example, if 8 requests all wait for an average of 1000 milliseconds, 8000 is reported. Unit: Milliseconds The only statistic that should be used for this metric is Sum. Do not use Average.
ethtool_bw_in_allowance_exceeded	The number of packets queued and/or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
ethtool_bw_out_allowance_exceeded	The number of packets queued and/or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
ethtool_conntrack_allowance_exceeded	The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
ethtool_linklocal_allowance_exceeded	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
ethtool_pps_allowance_exceeded	The number of packets queued and/or dropped because the bidirectional PPS exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics. Unit: None
mem_active	The amount of memory that has been used in some way during the last sample period. Unit: Bytes
mem_available	The amount of memory that is available and can be given instantly to processes. Unit: Bytes
mem_available_percent	The percentage of memory that is available and can be given instantly to processes. Unit: Percent
mem_buffered	The amount of memory that is being used for buffers. Unit: Bytes
mem_cached	The amount of memory that is being used for file caches. Unit: Bytes

Metric	Description
mem_free	The amount of memory that isn't being used. Unit: Bytes
mem_inactive	The amount of memory that hasn't been used in some way during the last sample period Unit: Bytes
mem_total	The total amount of memory. Unit: Bytes
mem_used	The amount of memory currently in use. Unit: Bytes
mem_used_percent	The percentage of memory currently in use. Unit: Percent
net_bytes_recv	The number of bytes received by the network interface. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.
net_bytes_sent	The number of bytes sent by the network interface. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
net_drop_in	The number of packets received by this network interface that were dropped. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_drop_out	The number of packets transmitted by this network interface that were dropped. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_err_in	The number of receive errors detected by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_err_out	The number of transmit errors detected by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_packets_sent	The number of packets sent by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
net_packets_recv	The number of packets received by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
netstat_tcp_close	The number of TCP connections with no state. Unit: Count
netstat_tcp_close_wait	The number of TCP connections waiting for a termination request from the client. Unit: Count
netstat_tcp_closing	The number of TCP connections that are waiting for a termination request with acknowledgment from the client. Unit: Count
netstat_tcp_established	The number of TCP connections established. Unit: Count
netstat_tcp_fin_wait1	The number of TCP connections in the FIN_WAIT1 state during the process of closing a connection. Unit: Count
netstat_tcp_fin_wait2	The number of TCP connections in the FIN_WAIT2 state during the process of closing a connection. Unit: Count

Metric	Description
netstat_tcp_last_ack	The number of TCP connections waiting for the client to send acknowledgment of the connectio n termination message. This is the last state right before the connection is closed down. Unit: Count
netstat_tcp_listen	The number of TCP ports currently listening for a connection request. Unit: Count
netstat_tcp_none	The number of TCP connections with inactive clients. Unit: Count
netstat_tcp_syn_sent	The number of TCP connections waiting for a matching connection request after having sent a connection request. Unit: Count
netstat_tcp_syn_recv	The number of TCP connections waiting for connection request acknowledgment after having sent and received a connection request. Unit: Count
netstat_tcp_time_wait	The number of TCP connections currently waiting to ensure that the client received the acknowledgment of its connection termination request. Unit: Count
netstat_udp_socket	The number of current UDP connections. Unit: Count

Metric	Description
processes_blocked	The number of processes that are blocked. Unit: Count
processes_dead	The number of processes that are dead, indicated by the X state code on Linux. This metric is not collected on macOS computers. Unit: Count
processes_idle	The number of processes that are idle (sleeping for more than 20 seconds). Available only on FreeBSD instances. Unit: Count
processes_paging	The number of processes that are paging, indicated by the W state code on Linux. This metric is not collected on macOS computers. Unit: Count
processes_running	The number of processes that are running, indicated by the R state code. Unit: Count
processes_sleeping	The number of processes that are sleeping, indicated by the S state code. Unit: Count
processes_stopped	The number of processes that are stopped, indicated by the T state code. Unit: Count

Metric	Description
processes_total	The total number of processes on the instance. Unit: Count
processes_total_threads	The total number of threads making up the processes. This metric is available only on Linux instances. This metric is not collected on macOS computers. Unit: Count
processes_wait	The number of processes that are paging, indicated by the W state code on FreeBSD instances. This metric is available only on FreeBSD instances, and is not available on Linux, Windows Server, or macOS instances. Unit: Count
processes_zombies	The number of zombie processes, indicated by the Z state code. Unit: Count
swap_free	The amount of swap space that isn't being used. Unit: Bytes
swap_used	The amount of swap space currently in use. Unit: Bytes
swap_used_percent	The percentage of swap space currently in use. Unit: Percent

Definitions of memory metrics collected by the CloudWatch agent

When the CloudWatch agent collects memory metrics, the source is the host's memory management subsystem. For example, the Linux kernel exposes OS-maintained data in `/proc`. For memory, the data is in `/proc/meminfo`.

Each different operating system and architecture has different calculations of the resources that are used by processes. For more information, see the following sections.

During each collection interval, the CloudWatch agent on each instance collects the instance resources and calculates the resources being used by all processes which are running in that instance. This information is reported back to CloudWatch metrics. You can configure the length of the collection interval in the CloudWatch agent configuration file. For more information, see CloudWatch agent configuration file: Agent section.

The following list explains how the memory metrics that the CloudWatch agent collects are defined.

- **Active Memory**– Memory that is being used by a process. In other words, the memory used by current running apps.
- **Available Memory**– The memory that can be instantly given to the processes without the system going into swap (also known as virtual memory).
- **Buffer Memory**– The data area shared by hardware devices or program processes that operate at different speeds and priorities.
- **Cached Memory**– Stores program instructions and data that are used repeatedly in the operation of programs that the CPU is likely to need next.
- **Free Memory**– Memory that is not being used at all and is readily available. It is completely free for the system to be used when needed.
- **Inactive Memory**– Pages that have not been accessed "recently".
- **Total Memory**– The size of the actual physical memory RAM.
- **Used Memory**– Memory that is currently in use by programs and processes.

Topics

- Linux: Metrics collected and calculations used
- macOS: Metrics collected and calculations used

- Windows: Metrics collected
- Example: Calculating memory metrics on Linux

Linux: Metrics collected and calculations used

Metrics collected and units:

- Active (Bytes)
- Available (Bytes)
- Available Percent (Percent)
- Buffered (Bytes)
- Cached (Bytes)
- Free (Bytes)
- Inactive (Bytes)
- Total (Bytes)
- Used (Bytes)
- Used Percent (Percent)

Used memory = Total Memory - Free Memory - Cached memory - Buffer memory

Total memory = Used Memory + Free Memory + Cached memory + Buffer memory

macOS: Metrics collected and calculations used

Metrics collected and units:

- Active (Bytes)
- Available (Bytes)
- Available Percent (Percent)
- Free (Bytes)
- Inactive (Bytes)
- Total (Bytes)
- Used (Bytes)

- Used Percent (Percent)

Available memory = Free Memory + Inactive memory

Used memory = Total Memory - Available memory

Total memory = Available Memory + Used Memory

Windows: Metrics collected

The metrics collected on Windows hosts are listed below. All of these metrics have None for `Unit`.

- Available bytes
- Cache Faults/sec
- Page Faults/sec
- Pages/sec

There are no calculations used for Windows metrics because the CloudWatch agent parses events from performance counters.

Example: Calculating memory metrics on Linux

As an example, suppose that entering the **`cat /proc/meminfo`** command on a Linux host shows the following results:

```
MemTotal:       3824388 kB
MemFree:         462704 kB
MemAvailable:   2157328 kB
Buffers:         126268 kB
Cached:         1560520 kB
SReclaimable:    289080 kB>
```

In this example, the CloudWatch agent will collect the following values. All the values that the CloudWatch agent collects and reports are in bytes.

- `mem_total`: 3916173312 bytes
- `mem_available`: 2209103872 bytes (MemFree + Cached)
- `mem_free`: 473808896 bytes
- `mem_cached`: 1893990400 bytes (`cached` + `SReclaimable`

- `mem_used`: 1419075584 bytes (`MemTotal` – (`MemFree` + `Buffers` + (`Cached` + `SReclaimable`)))
- `mem_buffered`: 129667072 bytes
- `mem_available_percent`: 56.41%
- `mem_used_percent`: 36.24% (`mem_used` / `mem_total`) * 100

Using the CloudWatch agent with related telemetry

Metrics and logs that are sent to CloudWatch can include an optional entity to correlate telemetry. Entities are used in the Explore related pane. The CloudWatch agent sends entities with a service name and environment name included.

The agent chooses the service name and environment name from the following data.

Service name

The agent chooses the service name from the following options, in priority order:

- **Application Signals instrumentation** – The agent sends the service name used by Application Signals. This can be overwritten by changing the `OTEL_SERVICE_NAME` environment variable used by supported OpenTelemetry instrumentation libraries.
- **CloudWatch agent configuration** – You can configure the agent to use a specific service name. This can be configured at the agent, plugin, metrics, logs, or log file level.
- **Kubernetes workload name** – For Kubernetes workloads, the agent sends the name of the workload for the corresponding pod, in the following priority order.
  - Deployment name
  - ReplicaSet name
  - StatefulSet name
  - DaemonSet name
  - CronJob name
  - Job name
  - Pod name
  - Container name
- **Resource tags from instance metadata** – For Amazon EC2 workloads, the agent sends the a name from tags, in the following order.

- service
- application
- app

You must setup instance metadata for the agent to be able to access tags.

- **Default** – If no other service name is found, the agent will send the name `Unknown`.

Environment name

The agent chooses the environment name from the following options, in priority order:

- **Application Signals instrumentation** – The agent sends the environment name used by Application Signals. This can be overwritten by setting a `deployment.environment` environment variable used by supported OpenTelemetry instrumentation libraries. For example, applications may set the environment variable `OTEL_RESOURCE_ATTRIBUTES=deployment.environment=MyEnvironment`.
- **CloudWatch agent configuration** – You can configure the agent to use a specific environment name. This can be configured at the agent, plugin, metrics, logs, or log file level.
- **Cluster name and workspace** – For Amazon EKS, `eks:`*`cluster-name`*`/`*`Namespace`*. For native Kubernetes running on Amazon EC2, `k8s:`*`cluster-name`*`/`*`Namespace`*.
- **Resource tags from instance metadata** – For Amazon EC2 workloads, the agent can will use the `AutoScalingGroup` tag.

  You must setup instance metadata for the agent to be able to access tags.
- By default, Amazon EC2 instances that aren't running Kubernetes will get the environment name `ec2:default`.

Common scenarios with the CloudWatch agent

This section provides you with different scenarios that outline how to complete common configuration and customization tasks for the CloudWatch agent.

Topics

- Running the CloudWatch agent as a different user
- How the CloudWatch agent handles sparse log files

- Adding custom dimensions to metrics collected by the CloudWatch agent
- Aggregating or rolling up metrics collected by the CloudWatch agent
- Collecting high-resolution metrics with the CloudWatch agent
- Sending metrics, logs, and traces to a different account
- Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent
- Appending OpenTelemetry collector configuration files

Running the CloudWatch agent as a different user

On Linux servers, the CloudWatch runs as the root user by default. To have the agent run as a different user, use the `run_as_user` parameter in the `agent` section in the CloudWatch agent configuration file. This option is available only on Linux servers.

If you're already running the agent with the root user and want to change to using a different user, use one of the following procedures.

To run the CloudWatch agent as a different user on an EC2 instance running Linux

1. Download and install a new CloudWatch agent package.
2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.
3. Provide credentials for this user in one of these ways:
   - If the file `.aws/credentials` exists in the home directory of the root user, you must create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be /home/*username*/`.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
   - If the file `.aws/credentials` does not exist in the home directory of the root user, you can do one of the following:
     - Create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be /home/*username*/`.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.

- Instead of creating a credentials file, attach an IAM role to the instance. The agent uses this role as the credential provider.

4. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

   Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch agent configuration file

5. Give the user the required permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.

6. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c file:configuration-file-path
```

To run the CloudWatch agent as a different user on an on-premises server running Linux

1. Download and install a new CloudWatch agent package.

2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.

3. Store the credentials of this user to a path that the user can access, such as `/home/username/.aws/credentials`.

4. Set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.

5. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

   Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch agent configuration file

6. Give the user required permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.

7. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c file:configuration-file-path
```

How the CloudWatch agent handles sparse log files

Sparse files are files with both empty blocks and real contents. A sparse file uses disk space more efficiently by writing brief information representing the empty blocks to disk instead of the actual null bytes which makes up the block. This makes the actual size of a sparse file usually much smaller than its apparent size.

However, the CloudWatch agent doesn't treat sparse files differently than it treats normal files. When the agent reads a sparse file, the empty blocks are treated as "real" blocks filled with null bytes. Because of this, the CloudWatch agent publishes as many bytes as the apparent size of a sparse file to CloudWatch.

Configuring the CloudWatch agent to publish a sparse file can cause higher than expected CloudWatch costs, so we recommend not to do so. For example, `/var/logs/lastlog` in Linux is usually a very sparse file, and we recommend that you don't publish it to CloudWatch.

Adding custom dimensions to metrics collected by the CloudWatch agent

To add custom dimensions such as tags to metrics collected by the agent, add the `append_dimensions` field to the section of the agent configuration file that lists those metrics.

For example, the following example section of the configuration file adds a custom dimension named `stackName` with a value of `Prod` to the `cpu` and `disk` metrics collected by the agent.

```
"cpu":{
  "resources":[
    "*"
  ],
  "measurement":[
    "cpu_usage_guest",
    "cpu_usage_nice",
    "cpu_usage_idle"
  ],
```

```
  "totalcpu":false,
  "append_dimensions":{
    "stackName":"Prod"
  }
},
"disk":{
  "resources":[
    "/",
    "/tmp"
  ],
  "measurement":[
    "total",
    "used"
  ],
  "append_dimensions":{
    "stackName":"Prod"
  }
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Aggregating or rolling up metrics collected by the CloudWatch agent

To aggregate or roll up metrics collected by the agent, add an `aggregation_dimensions` field to the section for that metric in the agent configuration file.

For example, the following configuration file snippet rolls up metrics on the `AutoScalingGroupName` dimension. The metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [["AutoScalingGroupName"]]
}
```

To roll up along the combination of each `InstanceId` and `InstanceType` dimensions in addition to rolling up on the Auto Scaling group name, add the following.

```
"metrics": {
```

```
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [["AutoScalingGroupName"], ["InstanceId", "InstanceType"]]
}
```

To roll up metrics into one collection instead, use `[]`.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [[]]
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Collecting high-resolution metrics with the CloudWatch agent

The `metrics_collection_interval` field specifies the time interval for the metrics collected, in seconds. By specifying a value of less than 60 for this field, the metrics are collected as high-resolution metrics.

For example, if your metrics should all be high-resolution and collected every 10 seconds, specify 10 as the value for `metrics_collection_interval` under the `agent` section as a global metrics collection interval.

```
"agent": {
  "metrics_collection_interval": 10
}
```

Alternatively, the following example sets the `cpu` metrics to be collected every second, and all other metrics are collected every minute.

```
"agent":{
  "metrics_collection_interval": 60
},
"metrics":{
  "metrics_collected":{
    "cpu":{
      "resources":[
```

```
        "*"
      ],
      "measurement":[
        "cpu_usage_guest"
      ],
      "totalcpu":false,
      "metrics_collection_interval": 1
    },
    "disk":{
      "resources":[
        "/",
        "/tmp"
      ],
      "measurement":[
        "total",
        "used"
      ]
    }
  }
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Sending metrics, logs, and traces to a different account

To have the CloudWatch agent send the metrics, logs, or traces to a different account, specify a `role_arn` parameter in the agent configuration file on the sending server. The `role_arn` value specifies an IAM role in the target account that the agent uses when sending data to the target account. This role enables the sending account to assume a corresponding role in the target account when delivering the metrics or logs to the target account.

You can also specify separate `role_arn` strings in the agent configuration file: one to use when sending metrics, another for sending logs, and another for sending traces.

The following example of part of the `agent` section of the configuration file sets the agent to use `CrossAccountAgentRole` when sending data to a different account.

```
{
  "agent": {
    "credentials": {
```

```
      "role_arn": "arn:aws:iam::123456789012:role/CrossAccountAgentRole"
    }
  },
  .....
}
```

Alternatively, the following example sets different roles for the sending account to use for sending metrics, logs, and traces:

```
"metrics": {
    "credentials": {
     "role_arn": "RoleToSendMetrics"
    },
    "metrics_collected": {....
```

```
"logs": {
    "credentials": {
    "role_arn": "RoleToSendLogs"
    },
    ....
```

Policies needed

When you specify a `role_arn` in the agent configuration file, you must also make sure the IAM roles of the sending and target accounts have certain policies. The roles in both the sending and target accounts should have `CloudWatchAgentServerPolicy`. For more information about assigning this policy to a role, see Prerequisites.

The role in the sending account also must include the following policy. You add this policy on the **Permissions** tab in the IAM console when you edit the role.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```

```
            "Action": [
                "sts:AssumeRole"
            ],
            "Resource": [
                "arn:aws:iam::111122223333:role/agent-role-in-target-account"
            ]
        }
    ]
}
```

The role in the target account must include the following policy so that it recognizes the IAM role used by the sending account. You add this policy on the **Trust relationships** tab in the IAM console when you edit the role. This role is the role specified in *agent-role-in-target-account* in the policy used by the sending account.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:role/role-in-sender-account"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent

The CloudWatch agent supports a different set of symbols for timestamp formats, compared to the earlier CloudWatch Logs agent. These differences are shown in the following table.

Symbols supported by both agents	Symbols supported only by CloudWatch agent	Symbols supported only by earlier CloudWatch Logs agent
%A, %a, %b, %B, %d, %f, %H, %l, %m, %M, %p, %S, %y, %Y, %Z, %z	%-d, %-l, %-m, %-M, %-S	%c,%j, %U, %W, %w

For more information about the meanings of the symbols supported by the new CloudWatch agent, see CloudWatch Agent Configuration File: Logs Section in the *Amazon CloudWatch User Guide*. For information about symbols supported by the CloudWatch Logs agent, see Agent Configuration File in the *Amazon CloudWatch Logs User Guide*.

Appending OpenTelemetry collector configuration files

The CloudWatch agent supports supplemental OpenTelemetry collector configuration files alongside its own configuration files. This feature allows you to use CloudWatch agent features such as CloudWatch Application Signals or Container Insights through the CloudWatch agent configuration and bring in your existing OpenTelemetry collector configuration with a single agent.

To prevent merge conflicts with pipelines automatically created by CloudWatch agent, we recommend that you add a custom suffix to each of the components and pipelines in your OpenTelemetry collector configuration.

```
receivers:
  otlp/custom-suffix:
    protocols:
      http:

exporters:
  awscloudwatchlogs/custom-suffix:
    log_group_name: "test-group"
    log_stream_name: "test-stream"

service:
  pipelines:
    logs/custom-suffix:
      receivers: [otlp/custom-suffix]
      exporters: [awscloudwatchlogs/custom-suffix]
```

To configure the CloudWatch agent, start the CloudWatch agent using the `fetch-config` option and specify the CloudWatch agent's configuration file. CloudWatch agent requires at least one CloudWatch agent configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -c
 file:/tmp/agent.json -s
```

Next, use the `append-config` option while specifying the OpenTelemetry collector configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -c
 file:/tmp/otel.yaml -s
```

The agent merges the two configuration files on start up and logs the resolved configuration.

CloudWatch agent credentials preference

This section outlines the credentials provider chain the CloudWatch agent uses to obtain credentials when communicating with other AWS services and APIs. The ordering is as follows:

> **Note**
>
> The preferences listed in numbers two through five are the same preference order as defined in the AWS SDK. For more information, see Specifying Credentials in the SDK documentation.

1. Shared config and credentials files as defined in the CloudWatch agent's `common-config.toml` file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
2. AWS SDK environment variables

> **Important**
>
> On Linux, if you run the CloudWatch agent using the `amazon-cloudwatch-agent-ctl` script, the script starts the agent as a `systemd` service. In this case, environment

variables such as `HOME`, `AWS_ACCESS_KEY_ID`, and `AWS_SECRET_ACCESS_KEY` are not accessible by the agent.

3. Shared configuration and credentials files found in `$HOME/%USERPROFILE%`

> **Note**
>
> The CloudWatch agent looks for `.aws/credentials` in `$HOME` for Linux and MacOS and looks in `%USERPROFILE%` for Windows. Unlike the AWS SDK, the CloudWatch agent does not have fallback methods to determine the home directory if the environment variables are inaccessible. This difference in behavior is to maintain backwards compatibility with earlier implementations of the AWS SDK.
> Furthermore, unlike with the shared credentials found in `common-config.toml`, if the AWS SDK-derived shared credentials expire and are rotated, the renewed credentials are not automatically picked up by the CloudWatch agent and require a restart of the agent to do so.

4. An AWS Identity and Access Management role for tasks if an application is present that uses an Amazon Elastic Container Service task definition or a RunTask API operation.
5. An instance profile attached to an Amazon EC2 instance.

As a best practice, we recommend that you specify credentials in the following order when you use the CloudWatch agent.

1. Use IAM roles for tasks if your application uses an Amazon Elastic Container Service task definition or a RunTask API operation.
2. Use IAM roles if your application runs on an Amazon EC2 instance.
3. Use the CloudWatch agent `common-config.toml` file to specify the credentials file. This credentials file is the same one used by other AWS SDKs and the AWS CLI. If you're already using a shared credentials file, you can also use it for this purpose. If you provide it by using the CloudWatch agent's `common-config.toml` file, you ensure that the agent will consume rotated credentials when they expire and get replaced without requiring you to restart the agent.
4. Use environment variables. Setting environment variables is useful if you're doing development work on a computer other than an Amazon EC2 instance.

> **Note**
>
> If you send telemetry to a different account as explained in Sending metrics, logs, and traces to a different account, the CloudWatch agent uses the credentials provider chain described in this section to obtain the initial set of credentials. It then uses those credentials when assuming the IAM role specified by `role_arn` in the CloudWatch agent configuration file.

Troubleshooting the CloudWatch agent

You can use the information in this section to troubleshoot issues you might encounter with the CloudWatch agent.

When encountering issues with the CloudWatch agent, you can use the `AWSSupport-TroubleshootCloudWatchAgent` automation runbook. The AWS troubleshooting tool can:

- Verify IAM permissions and instance profiles
- Check agent status and analyze logs
- Test endpoint connectivity
- Automatically collect and upload relevant logs to Amazon S3

For detailed information on the AWS troubleshooting tool, see Support Automation Workflow (SAW) Runbook - Troubleshoot CloudWatch agent.

Topics

- CloudWatch agent command line parameters
- Install the CloudWatch agent using Run Command fails
- The CloudWatch agent won't start
- Verify that the CloudWatch agent is running
- The CloudWatch agent won't start, and the error mentions an Amazon EC2 Region
- The CloudWatch agent won't start on Windows Server
- Where are the metrics?
- The CloudWatch agent takes a long time to run in a container or logs a hop limit error

- I updated my agent configuration but don't see the new metrics or logs in the CloudWatch console
- CloudWatch agent files and locations
- Finding information about CloudWatch agent versions
- Logs generated by the CloudWatch agent
- Stopping and restarting the CloudWatch agent

CloudWatch agent command line parameters

To see the full list of parameters supported by the CloudWatch agent, enter the following at the command line at a computer where you have it installed:

```
amazon-cloudwatch-agent-ctl -help
```

Install the CloudWatch agent using Run Command fails

To install the CloudWatch agent using Systems Manager Run Command, the SSM Agent on the target server must be version 2.2.93.0 or later of the SSM Agent agent. If your SSM Agent isn't the correct version, you might see errors that include the following messages:

```
no latest version found for package AmazonCloudWatchAgent on platform linux
```

```
failed to download installation package reliably
```

For information about updating your SSM Agent version, see Installing and Configuring SSM Agent in the *AWS Systems Manager User Guide*.

The CloudWatch agent won't start

If the CloudWatch agent fails to start, there might be an issue in your configuration. Configuration information is logged in the `configuration-validation.log` file. This file is located in `/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log` on Linux servers and in `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log` on servers running Windows Server.

Verify that the CloudWatch agent is running

You can query the CloudWatch agent to find whether it's running or stopped. You can use AWS Systems Manager to do this remotely. You can also use the command line, but only to check the local server.

To query the status of the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Action** list, choose **status**.
6. For **Optional Configuration Source** choose **default** and keep **Optional Configuration Location** blank.
7. In the **Target** area, choose the instance to check.
8. Choose **Run**.

If the agent is running, the output resembles the following.

```
{
       "status": "running",
       "starttime": "2017-12-12T18:41:18",
       "version": "1.73.4"
}
```

If the agent is stopped, the `"status"` field displays `"stopped"`.

To query the status of the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a
 status
```

On a server running Windows Server, enter the following in PowerShell as an administrator:

```
& $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m
 ec2 -a status
```

The CloudWatch agent won't start, and the error mentions an Amazon EC2 Region

If the agent doesn't start and the error message mentions an Amazon EC2 Region endpoint, you might have configured the agent to need access to the Amazon EC2 endpoint without granting that access.

For example, if you specify a value for the `append_dimensions` parameter in the agent configuration file that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the *Amazon Web Services General Reference*.

The CloudWatch agent won't start on Windows Server

On Windows Server, you might see the following error:

```
Start-Service : Service 'Amazon CloudWatch Agent (AmazonCloudWatchAgent)' cannot be
 started due to the following
error: Cannot start service AmazonCloudWatchAgent on computer '.'.
At C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1:113
 char:12
+     $svc | Start-Service
+            ~~~~~~~~~~~~~
    + CategoryInfo          : OpenError:
 (System.ServiceProcess.ServiceController:ServiceController) [Start-Service],
   ServiceCommandException
    + FullyQualifiedErrorId :
 CouldNotStartService,Microsoft.PowerShell.Commands.StartServiceCommand
```

To fix this, first make sure that the server service is running. This error can be seen if the agent tries to start when the server service isn't running.

If the server service is already running, the following may be the issue. On some Windows Server installations, the CloudWatch agent takes more than 30 seconds to start. Because Windows Server, by default, allows only 30 seconds for services to start, this causes the agent to fail with an error similar to the following:

To fix this issue, increase the service timeout value. For more information, see A service does not start, and events 7000 and 7011 are logged in the Windows event log.

Where are the metrics?

If the CloudWatch agent has been running but you can't find metrics collected by it in the AWS Management Console or the AWS CLI, confirm that you're using the correct namespace. By default, the namespace for metrics collected by the agent is `CWAgent`. You can customize this namespace using the `namespace` field in the `metrics` section of the agent configuration file. If you don't see the metrics that you expect, check the configuration file to confirm the namespace being used.

When you first download the CloudWatch agent package, the agent configuration file is `amazon-cloudwatch-agent.json`. This file is in the directory where you ran the configuration wizard, or you might have moved it to a different directory. If you use the configuration wizard, the agent configuration file output from the wizard is named `config.json`. For more information about the configuration file, including the `namespace` field, see CloudWatch agent configuration file: Metrics section.

The CloudWatch agent takes a long time to run in a container or logs a hop limit error

When you run the CloudWatch agent as a container service and want to add Amazon EC2 metric dimensions to all metrics collected by the agent, you might see the following errors in version v1.247354.0 of the agent:

```
2022-06-07T03:36:11Z E! [processors.ec2tagger] ec2tagger: Unable to retrieve Instance
 Metadata Tags. This plugin must only be used on an EC2 instance.
2022-06-07T03:36:11Z E! [processors.ec2tagger] ec2tagger: Please increase hop limit
 to 2 by following this document https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/
configuring-instance-metadata-options.html#configuring-IMDS-existing-instances.
2022-06-07T03:36:11Z E! [telegraf] Error running agent: could not initialize processor
 ec2tagger: EC2MetadataRequestError: failed to get EC2 instance identity document
```

```
caused by: EC2MetadataError: failed to make EC2Metadata request
        status code: 401, request id:
caused by:
```

You might see this error if the agent tries to get metadata from IMDSv2 inside a container without an appropriate hop limit. In versions of the agent earlier than v1.247354.0, you can experience this issue without seeing the log message.

To solve this, increase the hop limit to 2 by following the instructions in Configure the instance metadata options.

I updated my agent configuration but don't see the new metrics or logs in the CloudWatch console

If you update your CloudWatch agent configuration file, the next time that you start the agent, you need to use the **`fetch-config`** option. For example, if you stored the updated file on the local computer, enter the following command:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -s -m ec2 -c file:configuration-file-path
```

CloudWatch agent files and locations

The following table lists the files installed by and used with the CloudWatch agent, along with their locations on servers running Linux or Windows Server.

File	Linux location	Windows Server location
The control script that controls starting, stopping, and restarting the agent.	`/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl` or `/usr/bin/amazon-cloudwatch-agent-ctl`	`$Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1`
The log file the agent writes to. You might need to attach	`/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatc`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\ama`

File	Linux location	Windows Server location
this when contacting AWS Support.	`h-agent.log` or `/var/log/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.log`	`zon-cloudwatch-agent.log`
Agent configuration validation file.	`/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log` or `/var/log/amazon/amazon-cloudwatch-agent/configuration-validation.log`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log`
The JSON file used to configure the agent immediately after the wizard creates it. For more information, see Create the CloudWatch agent configuration file.	`/opt/aws/amazon-cloudwatch-agent/bin/config.json`	`$Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\config.json`
The JSON file used to configure the agent if this configuration file has been downloaded from Parameter Store.	`/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json` or `/etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.json`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json`

File	Linux location	Windows Server location
The TOML file used to specify Region and credential information to be used by the agent, overriding system defaults.	`/opt/aws/amazon-cloudwatch-agent/etc/common-config.toml` or `/etc/amazon/amazon-cloudwatch-agent/common-config.toml`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\common-config.toml`
The TOML file that contains the converted contents of the JSON configuration file. The `amazon-cloudwatch-agent-ctl` script generates this file. Users should not directly modify this file. It can be useful for verifying that JSON to TOML translation was successful.	`/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.toml` or `/etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.toml`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.toml`
The YAML file that contains the converted contents of the JSON configuration file. The `amazon-cloudwatch-agent-ctl` script generates this file. You should not directly modify this file. This file can be useful for verifying that the JSON to YAML translation was successful.	`/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.yaml` or `/etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.yaml`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.yaml`

Finding information about CloudWatch agent versions

To find the version number of the CloudWatch agent on a Linux server, enter the following command:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a status
```

To find the version number of the CloudWatch agent on Windows Server, enter the following command:

```
& $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m ec2
 -a status
```

> **Note**
>
> Using this command is the correct way to find the version of the CloudWatch agent. If you use **Programs and Features** in the Control Panel, you will see an incorrect version number.

You can also download a README file about the latest changes to the agent, and a file that indicates the version number that is currently available for download. These files are in the following locations:

- `https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/RELEASE_NOTES` or `https://amazoncloudwatch-agent-`*`us-east-1`*`.s3.`*`us-east-1`*`.amazonaws.com/info/latest/RELEASE_NOTES`
- `https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/CWAGENT_VERSION` or `https://amazoncloudwatch-agent-`*`us-east-1`*`.s3.`*`us-east-1`*`.amazonaws.com/info/latest/CWAGENT_VERSION`

Logs generated by the CloudWatch agent

The agent generates a log while it runs. This log includes troubleshooting information. This log is the `amazon-cloudwatch-agent.log` file. This file is located in `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` on Linux servers and in `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log` on servers running Windows Server.

You can configure the agent to log additional details in the `amazon-cloudwatch-agent.log` file. In the agent configuration file, in the `agent` section, set the `debug` field to `true`, then reconfigure and restart the CloudWatch agent. To disable the logging of this extra information, set the `debug` field to `false`. Then, reconfigure and restart the agent. For more information, see Manually create or edit the CloudWatch agent configuration file.

In versions 1.247350.0 and later of the CloudWatch agent, you can optionally set the `aws_sdk_log_level` field in the `agent` section of the agent configuration file to one or more of the following options. Separate multiple options with the `|` character.

- `LogDebug`
- `LogDebugWithSigning`
- `LogDebugWithHTTPBody`
- `LogDebugRequestRetries`
- `LogDebugWithEventStreamBody`

For more information about these options, see LogLevelType.

Stopping and restarting the CloudWatch agent

You can manually stop the CloudWatch agent using either AWS Systems Manager or the command line.

To stop the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, choose the instance where you installed the CloudWatch agent.
6. In the **Action** list, choose **stop**.
7. Keep **Optional Configuration Source** and **Optional Configuration Location** blank.

8. Choose **Run**.

To stop the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a
 stop
```

  On a server running Windows Server, enter the following in PowerShell as an administrator:

```
& $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m
 ec2 -a stop
```

To restart the agent, follow the instructions in (Optional) Modify the common configuration and named profile for CloudWatch agent.

Embedding metrics within logs

The CloudWatch embedded metric format allows you to generate custom metrics asynchronously in the form of logs written to CloudWatch Logs. You can embed custom metrics alongside detailed log event data, and CloudWatch automatically extracts the custom metrics so that you can visualize and alarm on them, for real-time incident detection. Additionally, the detailed log events associated with the extracted metrics can be queried using CloudWatch Logs Insights to provide deep insights into the root causes of operational events.

Embedded metric format helps you generate actionable custom metrics from ephemeral resources such as Lambda functions and containers. By using the embedded metric format to send logs from these ephemeral resources, you can now easily create custom metrics without having to instrument or maintain separate code, while gaining powerful analytical capabilities on your log data.

No setup is required to use the embedded metric format. Either structure your logs by following the Embedded metric format specification, or generate them using our client libraries and send them to CloudWatch Logs using the PutLogEvents API or the CloudWatch agent.

To generate metrics from logs with embedded metric format, you need the `logs:PutLogEvents` permission but you don't need to also have the `cloudwatch:PutMetricData` permission.

Charges are incurred for logs ingestion and archival, and custom metrics that are generated. For more information, see Amazon CloudWatch Pricing.

> **Note**
>
> Be careful when configuring your metric extraction as it impacts your custom metric usage and corresponding bill. If you unintentionally create metrics based on high-cardinality dimensions (such as `requestId`), the embedded metric format will by design create a custom metric corresponding to each unique dimension combination. For more information, see Dimensions.

The following topics describe how to publish logs using the embedded metric format, view your metrics and logs in the console, and set alarms on metrics created with the embedded metric format.

Topics

- Publishing logs with the embedded metric format
- Viewing your metrics and logs in the console
- Setting alarms on metrics created with the embedded metric format

Publishing logs with the embedded metric format

You can generate embedded metric format logs using the following methods:

- Generate and send the logs by using the open-sourced client libraries.
- Manually generate the logs using the embedded metric format specification, and then use the CloudWatch agent or the PutLogEvents API to send the logs.

The following topics provide more information about embedded metrics.

Topics

- Creating logs in embedded metric format using the client libraries
- Specification: Embedded metric format
- Using the PutLogEvents API to send manually-created embedded metric format logs
- Using the CloudWatch agent to send embedded metric format logs
- Using the embedded metric format with AWS Distro for OpenTelemetry

Creating logs in embedded metric format using the client libraries

You can use the open-sourced client libraries that Amazon provides to create embedded metric format logs. Full examples for different setups can be found in our client libraries under **/ examples**. The libraries and the instructions for how to use them are located on Github.

- Node.Js

> **Note**
>
> For Node.js, versions 4.1.1+, 3.0.2+, 2.0.7+ are required for use with the Lambda JSON log format. Using previous versions in such Lambda environments will lead to metric loss. For more information, see Accessing Amazon CloudWatch logs for AWS Lambda.

- Python
- Java
- C#

Client libraries are meant to work out of the box with the CloudWatch agent. Generated embedded metric format logs are sent to the CloudWatch agent, which then aggregates and publishes them to CloudWatch Logs for you.

> **Note**
>
> When using Lambda, no agent is required to send the logs to CloudWatch. Anything logged to STDOUT is sent to CloudWatch Logs via the Lambda Logging Agent.

Specification: Embedded metric format

The CloudWatch embedded metric format is a JSON specification used to instruct CloudWatch Logs to automatically extract metric values embedded in structured log events. You can use CloudWatch to graph and create alarms on the extracted metric values. This section describes embedded metric format specification conventions and the embedded metric format document structure.

Embedded metric format specification conventions

The key words “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” in this format specification are to be interpreted as described in Key Words RFC2119.

The terms "JSON", "JSON text", "JSON value", "member", "element", "object", "array", "number", "string", "boolean", "true", "false", and "null" in this format specification are to be interpreted as defined in JavaScript Object Notation RFC8259.

> **Note**
>
> If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

Embedded metric format document structure

This section describes the structure of an embedded metric format document. Embedded metric format documents are defined in JavaScript Object Notation RFC8259.

Unless otherwise noted, objects defined by this specification MUST NOT contain any additional members. Members not recognized by this specification MUST be ignored. Members defined in this specification are case-sensitive.

The embedded metric format is subject to the same limits as standard CloudWatch Logs events and are limited to a maximum size of 1 MB.

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `AWS/Logs` namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Root node

The LogEvent message MUST be a valid JSON object with no additional data at the beginning or end of the LogEvent message string. For more information about the LogEvent structure, see InputLogEvent.

Embedded metric format documents MUST contain the following top-level member on the root node. This is a Metadata object object.

```
{
 "_aws": {
    "CloudWatchMetrics": [ ... ]
  }
}
```

The root node MUST contain all Target members members defined by the references in the MetricDirective object.

The root node MAY contain any other members that are not included in the above requirements. The values of these members MUST be valid JSON types.

Metadata object

The _aws member can be used to represent metadata about the payload that informs downstream services how they should process the LogEvent. The value MUST be an object and MUST contain the following members:

- **CloudWatchMetrics**— An array of MetricDirective object used to instruct CloudWatch to extract metrics from the root node of the LogEvent.

```
{
  "_aws": {
    "CloudWatchMetrics": [ ... ]
  }
}
```

- **Timestamp**— A number representing the time stamp used for metrics extracted from the event. Values MUST be expressed as the number of milliseconds after Jan 1, 1970 00:00:00 UTC.

```
{
  "_aws": {
    "Timestamp": 1559748430481
  }
}
```

MetricDirective object

The MetricDirective object instructs downstream services that the LogEvent contains metrics that will be extracted and published to CloudWatch. MetricDirectives MUST contain the following members:

- **Namespace**— A string representing the CloudWatch namespace for the metric.
- **Dimensions**— A DimensionSet array.
- **Metrics**— An array of MetricDefinition objects. This array MUST NOT contain more than 100 MetricDefinition objects.

DimensionSet array

A DimensionSet is an array of strings containing the dimension keys that will be applied to all metrics in the document. The values within this array MUST also be members on the root-node—referred to as the Target members

A DimensionSet MUST NOT contain more than 30 dimension keys. A DimensionSet MAY be empty.

The target member MUST have a string value. This value MUST NOT contain more than 1024 characters. The target member defines a dimension that will be published as part of the metric identity. Every DimensionSet used creates a new metric in CloudWatch. For more information about dimensions, see Dimension and Dimensions.

```
{
 "_aws": {
   "CloudWatchMetrics": [
     {
       "Dimensions": [ [ "functionVersion" ] ],
       ...
     }
   ]
 },
 "functionVersion": "$LATEST"
}
```

Note

Be careful when configuring your metric extraction as it impacts your custom metric usage and corresponding bill. If you unintentionally create metrics based on high-cardinality dimensions (such as `requestId`), the embedded metric format will by design create a custom metric corresponding to each unique dimension combination. For more information, see Dimensions.

MetricDefinition object

A MetricDefinition is an object that MUST contain the following member:

- **Name**— A string Reference values to a metric Target members. Metric targets MUST be either a numeric value or an array of numeric values.

A MetricDefinition object MAY contain the following members:

- **Unit**— An OPTIONAL string value representing the unit of measure for the corresponding metric. Values SHOULD be valid CloudWatch metric units. For information about valid units, see MetricDatum. If a value is not provided, then a default value of NONE is assumed.
- **StorageResolution**— An OPTIONAL integer value representing the storage resolution for the corresponding metric. Setting this to 1 specifies this metric as a high-resolution metric, so that CloudWatch stores the metric with sub-minute resolution down to one second. Setting this to 60 specifies this metric as standard-resolution, which CloudWatch stores at 1-minute resolution. Values SHOULD be valid CloudWatch supported resolutions, 1 or 60. If a value is not provided, then a default value of 60 is assumed.

  For more information about high-resolution metrics, see High-resolution metrics.

> **Note**
>
> If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

```
{
  "_aws": {
    "CloudWatchMetrics": [
      {
        "Metrics": [
          {
            "Name": "Time",
            "Unit": "Milliseconds",
            "StorageResolution": 60
          }
        ],
        ...
      }
    ]
  },
  "Time": 1
}
```

Reference values

Reference values are string values that reference Target members members on the root node. These references should NOT be confused with the JSON Pointers described in RFC6901. Target values cannot be nested.

Target members

Valid targets MUST be members on the root node and cannot be nested objects. For example, a _reference_ value of `"A.a"` MUST match the following member:

```
{ "A.a" }
```

It MUST NOT match the nested member:

```
{ "A": { "a" } }
```

Valid values of target members depend on what is referencing them. A metric target MUST be a numeric value or an array of numeric values. Numeric array metric targets MUST NOT have more than 100 members. A dimension target MUST have a string value.

Embedded metric format example and JSON schema

The following is a valid example of embedded metric format.

```
{
  "_aws": {
    "Timestamp": 1574109732004,
    "CloudWatchMetrics": [
      {
        "Namespace": "lambda-function-metrics",
        "Dimensions": [["functionVersion"]],
        "Metrics": [
          {
            "Name": "time",
            "Unit": "Milliseconds",
            "StorageResolution": 60
          }
        ]
      }
    ]
```

```
  },
  "functionVersion": "$LATEST",
  "time": 100,
  "requestId": "989ffbf8-9ace-4817-a57c-e4dd734019ee"
}
```

You can use the following schema to validate embedded metric format documents.

```
{
    "type": "object",
    "title": "Root Node",
    "required": [
        "_aws"
    ],
    "properties": {
        "_aws": {
            "$id": "#/properties/_aws",
            "type": "object",
            "title": "Metadata",
            "required": [
                "Timestamp",
                "CloudWatchMetrics"
            ],
            "properties": {
                "Timestamp": {
                    "$id": "#/properties/_aws/properties/Timestamp",
                    "type": "integer",
                    "title": "The Timestamp Schema",
                    "examples": [
                        1565375354953
                    ]
                },
                "CloudWatchMetrics": {
                    "$id": "#/properties/_aws/properties/CloudWatchMetrics",
                    "type": "array",
                    "title": "MetricDirectives",
                    "items": {
                        "$id": "#/properties/_aws/properties/CloudWatchMetrics/items",

Second|Gigabits\\/Second|Terabits\\/Second|Count\\/Second|None)$"
                                        },
                                        "StorageResolution": {
                                            "$id": "#/properties/_aws/properties/
CloudWatchMetrics/items/properties/Metrics/items/properties/StorageResolution",
                                            "type": "integer",
                                            "title": "StorageResolution",
```

```
                                        "examples": [
                                            60
                                        ]
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}
```

Entity information in EMF format

When you publish logs to Amazon CloudWatch using Embedded Metric Format (EMF), you can include entity information in the log event. This section describes how to specify entity information and how CloudWatch processes this information.

Entity types

When no Entity is specified with the `PutLogEvents` request, CloudWatch will look for entity information in the EMF log content:

- **Service-type entities**

  Required fields: `Service` and `Environment`
- **Resource-type entities**

  Required fields: `ResourceType` and `Identifier`

Platform attributes

CloudWatch automatically determines the platform type based on these attributes:

- **Kubernetes (K8s):**

  Required: `K8s.Cluster`

Optional: `K8s.Namespace`, `K8s.Workload`, `K8s.Node`, `K8s.Pod`, `EC2.InstanceId`, `EC2.AutoScalingGroup`

- **Amazon EKS**

  Required: `EKS.Cluster`

  Optional: `K8s.Namespace`, `K8s.Workload`, `K8s.Node`, `K8s.Pod`, `EC2.InstanceId`
- **Amazon ECS:**

  Required: `ECS.Cluster`

  Optional: `ECS.Service`, `ECS.Task`
- **Amazon EC2**

  Required: `EC2.InstanceId`

  Optional: `EC2.AutoScalingGroup`
- **Lambda:**

  Required: `Lambda.Function`
- **Generic hosts:**

  Required: `Host`

Example EMF log format

```
{
    "_aws": {
        "CloudWatchMetrics": [
            {
                "Metrics": [
                    {"Name": "RequestLatency", "Unit": "Milliseconds"}
                ],
                "Namespace": "MyApplication"
            }
        ]
    },
    "Service": "PaymentService",
    "Environment": "Production",
```

```
    "K8s.Cluster": "main-cluster",
    "K8s.Namespace": "payment-ns",
    "K8s.Pod": "payment-pod-123",
    "K8s.Node": "worker-node-1",
    "K8s.Workload": "payment-deployment",
    "RequestLatency": 135.5,
    "timestamp": 1622163600000
}
```

Generated Entity

The above EMF log will generate the following Entity:

```
{
    "KeyAttributes": {
        "Type": "Service",
        "Name": "PaymentService",
        "Environment": "Production"
    },
    "Attributes": {
        "PlatformType": "K8s",
        "K8s.Cluster": "main-cluster",
        "K8s.Namespace": "payment-ns",
        "K8s.Pod": "payment-pod-123",
        "K8s.Node": "worker-node-1",
        "K8s.Workload": "payment-deployment"
    }
}
```

Entity processing

CloudWatch processes the entity information as follows:

- **KeyAttributes:**
  - Determines entity type based on required fields
  - For Service-type, extracts Service name and Environment
  - These become the primary identifiers for the entity
- **Attributes:**
  - Sets PlatformType based on included platform attributes
  - Includes all relevant platform-specific information

- Maintains relationship context for the telemetry data

CloudWatch uses this entity information to establish relationships between different pieces of telemetry data, enabling enhanced observability and contextual analysis of your applications and infrastructure. For more information, see How to add related information to custom telemetry sent to CloudWatch .

> **Note**
>
> Entity information helps CloudWatch create a complete picture of your application's telemetry data and its relationships within your infrastructure.

Using the PutLogEvents API to send manually-created embedded metric format logs

You can send embedded metric format logs to CloudWatch Logs using the CloudWatch Logs PutLogEvents API. When calling PutLogEvents, you have the option to include the following HTTP header, which tells CloudWatch Logs the metrics should be extracted, but it's not required.

```
x-amzn-logs-format: json/emf
```

The following is a full example using the AWS SDK for Java 2.x:

```
package org.example.basicapp;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatchlogs.CloudWatchLogsClient;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeLogStreamsRequest;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeLogStreamsResponse;
import software.amazon.awssdk.services.cloudwatchlogs.model.InputLogEvent;
import software.amazon.awssdk.services.cloudwatchlogs.model.PutLogEventsRequest;

import java.util.Collections;

public class EmbeddedMetricsExample {
        public static void main(String[] args) {
```

```
                final String usage = "To run this example, supply a Region code (eg.
 us-east-1), log group, and stream name as command line arguments"
                                + "Ex: PutLogEvents <region-id> <log-group-name>
 <stream-name>";

                if (args.length != 3) {
                        System.out.println(usage);
                        System.exit(1);
                }

                String regionId = args[0];
                String logGroupName = args[1];
                String logStreamName = args[2];

                CloudWatchLogsClient logsClient =
 CloudWatchLogsClient.builder().region(Region.of(regionId)).build();

                // Build a JSON log using the EmbeddedMetricFormat.
                long timestamp = System.currentTimeMillis();
                String message = "{" +
                                "  \"_aws\": {" +
                                "    \"Timestamp\": " + timestamp  + "," +
                                "    \"CloudWatchMetrics\": [" +
                                "      {" +
                                "        \"Namespace\": \"MyApp\"," +
                                "        \"Dimensions\": [[\"Operation\"], [\"Operation
\", \"Cell\"]]," +
                                "        \"Metrics\": [{ \"Name\": \"ProcessingLatency
\", \"Unit\": \"Milliseconds\", \"StorageResolution\": 60 }]" +
                                "      }" +
                                "    ]" +
                                "  }," +
                                "  \"Operation\": \"Aggregator\"," +
                                "  \"Cell\": \"001\"," +
                                "  \"ProcessingLatency\": 100" +
                                "}";
                InputLogEvent inputLogEvent = InputLogEvent.builder()
                        .message(message)
                        .timestamp(timestamp)
                        .build();

                // Specify the request parameters.
                PutLogEventsRequest putLogEventsRequest = PutLogEventsRequest.builder()
                        .logEvents(Collections.singletonList(inputLogEvent))
```

```
                        .logGroupName(logGroupName)
                        .logStreamName(logStreamName)
                        .build();

                logsClient.putLogEvents(putLogEventsRequest);

                System.out.println("Successfully put CloudWatch log event");
        }

}
```

Note

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `AWS/Logs` namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Using the CloudWatch agent to send embedded metric format logs

This section describes how to install and use the CloudWatch agent. The first part of this section describes how to install the CloudWatch agent. The the second part of this section describes how to use the CloudWatch agent to send embedded metric format logs. If you want to use this method, you must install the CloudWatch agent for the AWS services you want to send embedded metric format logs from. Then you can begin sending the events. The CloudWatch agent must be version 1.230621.0 or later.

Note

You do not need to install the CloudWatch agent to send logs from Lambda functions. Lambda function timeouts are not handled automatically. This means that if your function times out before the metrics get flushed, then the metrics for that invocation will not be captured.

Installing the CloudWatch agent

Install the CloudWatch agent for each service which is to send embedded metric format logs.

Installing the CloudWatch agent on EC2

First, install the CloudWatch agent on the instance. For more information, see Installing the CloudWatch agent.

Once you have installed the agent, configure the agent to listen on a UDP or TCP port for the embedded metric format logs. The following is an example of this configuration that listens on the default socket `tcp:25888`. For more information about agent configuration, see Manually create or edit the CloudWatch agent configuration file.

```
{
  "logs": {
    "metrics_collected": {
      "emf": { }
    }
  }
}
```

Installing the CloudWatch agent on Amazon ECS

The easiest way to deploy the CloudWatch agent on Amazon ECS is to run it as a sidecar, defining it in the same task definition as your application.

Create agent configuration file

Create your CloudWatch agent configuration file locally. In this example, the relative file path will be `amazon-cloudwatch-agent.json`.

For more information about agent configuration, see Manually create or edit the CloudWatch agent configuration file.

```
{
  "logs": {
    "metrics_collected": {
      "emf": { }
    }
  }
}
```

Push configuration to SSM Parameter Store

Enter the following command to push the CloudWatch agent configuration file to the AWS Systems Manager (SSM) Parameter Store.

```
aws ssm put-parameter \
    --name "cwagentconfig" \
    --type "String" \
    --value "`cat amazon-cloudwatch-agent.json`" \
    --region "{{region}}"
```

Configure the task definition

Configure your task definition to use the CloudWatch Agent and expose the TCP or UDP port. The sample task definition that you should use depends on your networking mode.

Notice that the `webapp` specifies the `AWS_EMF_AGENT_ENDPOINT` environment variable. This is used by the library and should point to the endpoint that the agent is listening on. Additionally, the `cwagent` specifies the `CW_CONFIG_CONTENT` as a "valueFrom" parameter that points to the SSM configuration that you created in the previous step.

This section contains one example for bridge mode and one example for host or awsvpc mode. For more examples of how you can configure the CloudWatch agent on Amazon ECS, see the Github samples repository

The following is an example for bridge mode. When bridge mode networking is enabled, the agent needs to be linked to your application using the `links` parameter and must be addressed using the container name.

```
{
  "containerDefinitions": [
          {
              "name": "webapp",
              "links": [ "cwagent" ],
              "image": "my-org/web-app:latest",
              "memory": 256,
              "cpu": 256,
              "environment": [{
                "name": "AWS_EMF_AGENT_ENDPOINT",
                "value": "tcp://cwagent:25888"
              }],
          },
          {
```

```
            "name": "cwagent",
            "mountPoints": [],
            "image": "public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest",
            "memory": 256,
            "cpu": 256,
            "portMappings": [{
                "protocol": "tcp",
                "containerPort": 25888
            }],
            "environment": [{
              "name": "CW_CONFIG_CONTENT",
              "valueFrom": "cwagentconfig"
            }],
        }
    ],
}
```

The following is an example for host mode or awsvpc mode. When running on these network modes, the agent can be addressed over `localhost`.

```
{
  "containerDefinitions": [
          {
              "name": "webapp",
              "image": "my-org/web-app:latest",
              "memory": 256,
              "cpu": 256,
              "environment": [{
                "name": "AWS_EMF_AGENT_ENDPOINT",
                "value": "tcp://127.0.0.1:25888"
              }],
          },
          {
              "name": "cwagent",
              "mountPoints": [],
              "image": "public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest",
              "memory": 256,
              "cpu": 256,
              "portMappings": [{
                  "protocol": "tcp",
                  "containerPort": 25888
              }],
              "environment": [{
```

```
                "name": "CW_CONFIG_CONTENT",
                "valueFrom": "cwagentconfig"
            }],
        }
    ],
}
```

Note

In awsvpc mode, you must either give a public IP address to the VPC (Fargate only), set up a NAT gateway, or set up a CloudWatch Logs VPC endpoint. For more information about setting up a NAT, see NAT Gateways. For more information about setting up a CloudWatch Logs VPC endpoint, see Using CloudWatch Logs with Interface VPC Endpoints.
The following is an example of how to assign a public IP address to a task that uses the Fargate launch type.

```
aws ecs run-task \
--cluster {{cluster-name}} \
--task-definition cwagent-fargate \
--region {{region}} \
--launch-type FARGATE \
--network-configuration
 "awsvpcConfiguration={subnets=[{{subnetId}}],securityGroups=[{{sgId}}],assignPublicIp=ENA
```

Ensure permissions

Ensure the IAM role executing your tasks has permission to read from the SSM Parameter Store. You can add this permission by attaching the **AmazonSSMReadOnlyAccess** policy. To do so, enter the following command.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonSSMReadOnlyAccess
 \
--role-name CWAgentECSExecutionRole
```

Installing the CloudWatch agent on Amazon EKS

Parts of this process can be skipped if you have already installed CloudWatch Container Insights on this cluster.

Permissions

If you have not already installed Container Insights, then first ensure that your Amazon EKS nodes have the appropriate IAM permissions. They should have the **CloudWatchAgentServerPolicy** attached. For more information, see Verifying prerequisites for Container Insights in CloudWatch.

Create ConfigMap

Create a ConfigMap for the agent. The ConfigMap also tells the agent to listen on a TCP or UDP port. Use the following ConfigMap.

```
# cwagent-emf-configmap.yaml
apiVersion: v1
data:
  # Any changes here must not break the JSON format
  cwagentconfig.json: |
    {
      "agent": {
        "omit_hostname": true
      },
      "logs": {
        "metrics_collected": {
          "emf": { }
        }
      }
    }
kind: ConfigMap
metadata:
  name: cwagentemfconfig
  namespace: default
```

If you have already installed Container Insights, add the following `"emf": { }` line to your existing ConfigMap.

Apply the ConfigMap

Enter the following command to apply the ConfigMap.

```
kubectl apply -f cwagent-emf-configmap.yaml
```

Deploy the agent

To deploy the CloudWatch agent as a sidecar, add the agent to your pod definition, as in the following example.

```
apiVersion: v1
kind: Pod
metadata:
  name: myapp
  namespace: default
spec:
  containers:
    # Your container definitions go here
    - name: web-app
      image: my-org/web-app:latest
    # CloudWatch Agent configuration
    - name: cloudwatch-agent
      image: public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest
      imagePullPolicy: Always
      resources:
        limits:
          cpu: 200m
          memory: 100Mi
        requests:
          cpu: 200m
          memory: 100Mi
      volumeMounts:
        - name: cwagentconfig
          mountPath: /etc/cwagentconfig
      ports:
  # this should match the port configured in the ConfigMap
        - protocol: TCP
          hostPort: 25888
          containerPort: 25888
  volumes:
    - name: cwagentconfig
      configMap:
        name: cwagentemfconfig
```

Using the CloudWatch agent to send embedded metric format logs

When you have the CloudWatch agent installed and running, you can send the embedded metric format logs over TCP or UDP. There are two requirements when sending the logs over the agent:

- The logs must contain a `LogGroupName` key that tells the agent which log group to use.

- Each log event must be on a single line. In other words, a log event cannot contain the newline (\n) character.

The log events must also follow the embedded metric format specification. For more information, see Specification: Embedded metric format.

If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

The following is an example of sending log events manually from a Linux bash shell. You can instead use the UDP socket interfaces provided by your programming language of choice.

```
echo '{"_aws":{"Timestamp":1574109732004,"LogGroupName":"Foo","CloudWatchMetrics":
[{"Namespace":"MyApp","Dimensions":[["Operation"]],"Metrics":
[{"Name":"ProcessingLatency","Unit":"Milliseconds","StorageResolution":60}]}]},"Operation":"Agg
 \
> /dev/udp/0.0.0.0/25888
```

Note

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the AWS/Logs namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Using the embedded metric format with AWS Distro for OpenTelemetry

OpenTelemetry is an open-source initiative that removes boundaries and restrictions between vendor-specific formats for tracing, logs, and metrics by offering a single set of specifications and APIs. For more information, see OpenTelemetry. You can use the embedded metric format as a part of the OpenTelemetry project. Using the embedded metric format with OpenTelemetry requires two components: an OpenTelemetry-compliant data source and the AWS Distro for OpenTelemetry Collector enabled for use with CloudWatch embedded metric format logs.

We have preconfigured redistributions of the OpenTelemetry components, which AWS maintains, to make onboarding as easy as possible. For more information about using OpenTelemetry with the embedded metric format, in addition to other AWS services, see AWS Distro for

OpenTelemetry. For additional information regarding language support and usage, see AWS Observability on Github.

Viewing your metrics and logs in the console

After you generate embedded metric format logs that extract metrics, you can use the CloudWatch console to view the metrics. Embedded metrics have the dimensions that you specified when you generated the logs. Also, the embedded metrics that you generated using the client libraries have the following default dimensions:

- ServiceType
- ServiceName
- LogGroup

This section describes how to view these metrics in the CloudWatch console and query your extracted metrics using CloudWatch Logs Insights.

To view metrics that were generated from embedded metric format logs

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Select a namespace that you specified for your embedded metrics when you generated them. If you used the client libraries to generate the metrics and did not specify a namespace, then select **aws-embedded-metrics**. This is the default namespace for embedded metrics generated using the client libraries.
4. Select a metric dimension (for example, **ServiceName**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To sort the table, use the column heading.

    b. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    c. To filter by resource, choose the resource ID and then choose **Add to search**.

    d. To filter by metric, choose the metric name and then choose **Add to search**.

Querying logs using CloudWatch Logs Insights

You can query the detailed log events associated with the extracted metrics by using CloudWatch Logs Insights to provide deep insights into the root causes of operational events. One of the benefits of extracting metrics from your logs is that you can filter your logs later by the unique metric (metric name plus unique dimension set) and metric values, to get context on the events that contributed to the aggregated metric value

For example, to get an impacted request id or x-ray trace id, you could run the following query in CloudWatch Logs Insights.

```
filter Latency > 1000 and Operation = "Aggregator"
| fields RequestId, TraceId
```

You can also perform query-time aggregation on high-cardinality keys, such as finding the customers impacted by an event. The following example illustrates this.

```
filter Latency > 1000 and Operation = "Aggregator"
| stats count() by CustomerId
```

For more information, see Analyzing Log Data with CloudWatch Logs Insights

Setting alarms on metrics created with the embedded metric format

In general, creating alarms on metrics generated by the embedded metric format follows the same pattern as creating alarms on any other metrics. For more information, see Using Amazon CloudWatch alarms. Embedded metric format metric generation depends on your log publishing flow because CloudWatch Logs needs to process logs so they can be transformed into metrics. It's important to publish logs in a timely manner, so that metric datapoints are created within the period of time that alarms are evaluated.

If you plan on using the embedded metric format to send high-resolution metrics and create alarms on these metrics, we recommended that you flush logs to CloudWatch Logs at an interval of 5 seconds or less to avoid introducing an additional delay, which can cause alarming on partial or missing data. If you are using the CloudWatch agent, you can adjust the flush interval by setting the `force_flush_interval` parameter in the CloudWatch agent configuration file. This value defaults to 5 seconds. If you are using Lambda on other platforms where you can't control the log flush interval, consider using "M out of N" alarms to control the number of datapoints used to alarm. For more information, see Evaluating an alarm.

AWS services that publish CloudWatch metrics

You can use the following table to learn which AWS services publish metrics to CloudWatch. For information about the metrics and dimensions, see the specified documentation.

Service	Namespace	Documentation
AWS Amplify	`AWS/AmplifyHosting`	Monitoring
Amazon API Gateway	`AWS/ApiGateway`	Monitor API Execution with Amazon CloudWatch
Amazon AppFlow	`AWS/AppFlow`	Monitoring Amazon AppFlow with Amazon CloudWatch
AWS Application Migration Service	`AWS/MGN`	Monitoring Application Migration Service with Amazon CloudWatch
AWS App Runner	`AWS/AppRunner`	Viewing App Runner service metrics reported to CloudWatch
AppStream 2.0	`AWS/AppStream`	Monitoring Amazon AppStream 2.0 Resources
AWS AppSync	`AWS/AppSync`	CloudWatch Metrics
Amazon Athena	`AWS/Athena`	Monitoring Athena Queries with CloudWatch Metrics
Amazon Aurora	`AWS/RDS`	Amazon Aurora metrics
AWS Backup	`AWS/Backup`	Monitoring AWS Backup Metrics with CloudWatch
Amazon Bedrock Guardrails	`AWS/Bedrock/Guardrails`	Monitoring Amazon Bedrock Guardrails using CloudWatch Metrics

Amazon WorkSpaces Web	`AWS/WorkSpacesWeb`	Monitoring Amazon WorkSpaces Web with Amazon CloudWatch

AWS usage metrics

CloudWatch collects metrics that track the usage of some AWS resources and APIs. These metrics are published in the `AWS/Usage` namespace. Usage metrics in CloudWatch allow you to proactively manage usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch outlier detection, and configuring alarms that alert you when usage approaches a threshold.

Some AWS services integrate these usage metrics with Service Quotas. For these services, you can use CloudWatch to manage your account's use of your service quotas. For more information, see Visualizing your service quotas and setting alarms.

Topics

- Visualizing your service quotas and setting alarms
- AWS API usage metrics
- CloudWatch usage metrics

Visualizing your service quotas and setting alarms

For some AWS services, you can use the usage metrics to visualize your current service usage on CloudWatch graphs and dashboards. You can use a CloudWatch metric math function to display the service quotas for those resources on your graphs. You can also configure alarms that alert you when your usage approaches a service quota. For more information about service quotas, see What Is Service Quotas in the *Service Quotas User Guide*.

If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can use that monitoring account to visualize service quotas and set alarms for metrics in the source accounts that are linked to that monitoring account. For more information, see CloudWatch cross-account observability.

The following services integrate their usage metrics with Service Quotas:

- AWS CloudHSM
- Amazon Chime SDK
- Amazon CloudWatch

- Amazon CloudWatch Logs
- Amazon DynamoDB
- Amazon EC2
- Amazon Elastic Container Registry
- Elastic Load Balancing
- AWS Fargate
- AWS Fault Injection Service
- AWS Interactive Video Service
- AWS Key Management Service
- Amazon Data Firehose
- Amazon Location Service
- Amazon Managed Blockchain (AMB) Query
- Amazon SageMaker AI
- Multi-party approval

To visualize a service quota and optionally set an alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. On the **All metrics** tab, choose **Usage**, and then choose **By AWS Resource**.

   The list of service quota usage metrics appears.
4. Select the check box next to one of the metrics.

   The graph displays your current usage of that AWS resource.
5. To add your service quota to the graph, do the following:

   a. Choose the **Graphed metrics** tab.

   b. Choose **Math expression**, **Start with an empty expression**. In the new row, under **Details**, enter **`SERVICE_QUOTA(m1)`**.

      A new line is added to the graph, displaying the service quota for the resource represented in the metric.

6. To see your current usage as a percentage of the quota, add a new expression or change the current **SERVICE_QUOTA** expression. The new expression to use is **`m1/SERVICE_QUOTA(m1)*100`**.
7. (Optional) To set an alarm that notifies you if you approach the service quota, do the following:

   a. On the row with **`m1/SERVICE_QUOTA(m1)*100`**, under **Actions**, choose the alarm icon. It looks like a bell.

      The alarm creation page appears.

   b. Under **Conditions**, ensure that **Threshold type** is **Static** and **Whenever Expression1 is** is set to **Greater**. Under **than**, enter **`80`**. This creates an alarm that goes into ALARM state when your usage exceeds 80 percent of the quota.

   c. Choose **Next**.

   d. On the next page, select an Amazon SNS topic or create a new one, and then choose **Next**. The topic you select is notified when the alarm goes to ALARM state.

   e. On the next page, enter a name and description for the alarm, and then choose **Next**.

   f. Choose **Create alarm**.

AWS API usage metrics

Most APIs that support AWS CloudTrail logging also report usage metrics to CloudWatch. API usage metrics in CloudWatch allow you to proactively manage API usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch outlier detection, and configuring alarms that alert when usage approaches a threshold.

You can use the he following table to learn about services that report API usage metrics to CloudWatch. The table lists the values to use for the `Service` dimension, so you can see the usage metrics from that service. You can use the procedure in this section to view the list of a service's APIs that report usage metrics to CloudWatch.

Service	Value for the `Service` dimension
AWS Identity and Access Management Access Analyzer	`Access Analyzer`

Service	Value for the Service dimension
AWS Account Management	Account Management
Alexa for Business	A4B
Amazon API Gateway	API Gateway
AWS App Mesh	App Mesh
AWS AppConfig	AWS AppConfig
Amazon AppFlow	AppFlow
Application Auto Scaling	Application Auto Scaling
Application Discovery Service	Application Discovery Service
Amazon AppStream	AppStream
AppStream 2.0 Image Builder	Image Builder
Amazon Athena	Athena
AWS Audit Manager	Audit Manager
AWS Backup	Backup
AWS Batch	Batch
Amazon Braket	Braket
AWS Budgets	Budgets
AWS Certificate Manager	Certificate Manager
Amazon Chime SDK	ChimeSDK
Amazon Cloud Directory	Cloud Directory
AWS Cloud Map	Cloud Map

Service	Value for the `Service` dimension
AWS CloudFormation	`CloudFormation`
AWS CloudHSM	`CloudHSM`
Amazon CloudSearch	`CloudSearch`
AWS CloudShell	`CloudShell`
AWS CloudTrail	`CloudTrail`
Amazon CloudWatch	`CloudWatch`
Amazon CloudWatch Application Signals	`CloudWatch Application Signals`
Amazon CloudWatch Logs	`Logs`
Amazon CloudWatch Application Insights	`CloudWatch Application Insights`
AWS CodeBuild	`CodeBuild`
AWS CodeCommit	`CodeCommit`
Amazon CodeGuru Profiler	`CodeGuru Profiler`
AWS CodePipeline	`CodePipeline`
AWS CodeStar	`CodeStar`
AWS CodeStar Notifications	`CodeStar Notifications`
AWS CodeStar Connections	`CodeStar Connections`
Amazon Cognito Identity pools	`Cognito Identity Pools`
Amazon Cognito Sync	`Cognito Sync`
Amazon Comprehend	`Comprehend`
Amazon Comprehend Medical	`Comprehend Medical`

Service	Value for the Service dimension
AWS Compute Optimizer	ComputeOptimzier
Amazon Connect	Connect
Amazon Connect Customer Profiles	Customer Profiles
AWS Cost and Usage Reports	Cost and Usage Report
AWS Cost Explorer	Cost Explorer
AWS Data Exchange	Data Exchange
AWS Data Lifecycle Manager	Data Lifecycle Manager
AWS Database Migration Service	Database Migration Service
AWS DataSync	DataSync
AWS DeepLens	AWS DeepLens
Amazon Detective	Detective
Device Advisor	Device Advisor
AWS Direct Connect	Direct Connect
AWS Directory Service	Directory Service
DynamoDB Accelerator	DynamoDBAccelerator
Amazon EC2	EC2
EC2 Auto Scaling	EC2 Auto Scaling
Amazon Elastic Container Registry	ECR Public
Amazon Elastic Container Service	ECS
Amazon Elastic File System	EFS

Service	Value for the `Service` dimension
Amazon Elastic Kubernetes Service	`EKS`
AWS Elastic Beanstalk	`Elastic Beanstalk`
Amazon Elastic Inference	`Elastic Inference`
Elastic Load Balancing	`Elastic Load Balancing`
Amazon EMR	`EMR Containers`
AWS Firewall Manager	`Firewall Manager`
Amazon FSx	`FSx`
Amazon GameLift Servers	`GameLift`
AWS Glue DataBrew	`DataBrew`
Amazon Managed Grafana	`Grafana`
AWS IoT Greengrass	`Greengrass`
AWS Ground Station	`Ground Station`
AWS Health APIs And Notifications	`AWS Health APIs And Notifications`
Amazon Interactive Video Service	`IVS`
AWS IoT Core	`IoT`
AWS IoT Events	`IoT Events`
AWS IoT RoboRunner	`IoT RoboRunner`
AWS IoT SiteWise	`IoT Sitewise`
AWS IoT Wireless	`IoT Wireless`
Amazon Kendra	`Kendra`

Service	Value for the Service dimension
Amazon Keyspaces (for Apache Cassandra)	Keyspaces
Amazon Managed Service for Apache Flink	Kinesis Analytics
Amazon Data Firehose	Firehose
Kinesis Video Streams	Kinesis Video Streams
AWS Key Management Service	KMS
AWS Lambda	Lambda
AWS Launch Wizard	Launch Wizard
Amazon Lex	Amazon Lex
Amazon Lightsail	Lightsail
Amazon Location Service	Location
Amazon Lookout for Vision	Lookout for Vision
Amazon Machine Learning	Amazon Machine Learning
Amazon Macie	Macie
Amazon Managed Blockchain (AMB) Query	Amazon Managed Blockchain Query
AWS Managed Services	AWS Managed Services
AWS Marketplace Commerce Analytics	Marketplace Analytics Service
AWS Elemental MediaConnect	MediaConnect
AWS Elemental MediaConvert	MediaConvert
AWS Elemental MediaLive	MediaLive
AWS Elemental MediaStore	Mediastore

Service	Value for the Service dimension
AWS Elemental MediaTailor	MediaTailor
AWS Mobile Hub	Mobile Hub
AWS Network Firewall	Network Firewall
OpsWorks	OpsWorks
OpsWorks for Configuration Management	OPsWorks CM
AWS Outposts	Outposts
AWS Organizations	Organizations
Amazon RDS Performance Insights	Performance Insights
Amazon Pinpoint	Pinpoint
AWS Private Certificate Authority	Private Certificate Authority
Amazon Managed Service for Prometheus	Prometheus
AWS Proton	Proton
Amazon Quantum Ledger Database (Amazon QLDB)	QLDB
Amazon RDS	RDS
Amazon Redshift	Redshift Data API
Amazon Rekognition	Rekognition
AWS Resource Access Manager	Resource Access Manager
AWS Resource Groups	Resource Groups
AWS Resource Groups Tagging API	Resource Groups Tagging API
Amazon Route 53 Domains	Route 53 Domains

Service	Value for the Service dimension
Amazon Route 53 Resolver	Route 53 Resolver
Amazon S3	S3
Amazon S3 Glacier	Amazon S3 Glacier
Amazon SageMaker Runtime	Sagemaker
Savings Plans	Savings Plans
AWS Secrets Manager	Secrets Manager
AWS Security Hub	Security Hub
AWS Server Migration Service	AWS Server Migration Service
AWS Service Catalog AppRegistry	Service Catalog AppRegistry
Service Quotas	Service Quotas
AWS Shield	Shield
AWS Signer	Signer
Amazon Simple Notification Service	SNS
Amazon Simple Email Service	SES
Amazon Simple Queue Service	SQS
Identity Store	Identity Store
Storage Gateway	Storage Gateway
AWS Support	Support
Amazon Simple Workflow Service	SWF
Amazon Textract	Textract

Service	Value for the Service dimension
AWS IoT Things Graph	ThingsGraph
Amazon Timestream	Timestream
Amazon Transcribe	Transcribe
Amazon Translate	Translate
Amazon Transcribe streaming transcription	Transcribe Streaming
AWS Transfer Family	Transfer
AWS WAF	WAF
Amazon WorkLink	WorkLink
Amazon WorkMail	Amazon WorkMail
Amazon WorkSpaces	Workspaces
AWS X-Ray	X-Ray

Some services report usage metrics for additional APIs as well. To see whether an API reports usage metrics to CloudWatch, use the CloudWatch console to see the metrics reported by that service in the AWS/Usage namespace.

To see the list of a service's APIs that report usage metrics to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. On the **All metrics** tab, choose **Usage**, and then choose **By AWS Resource**.
4. In the search box near the list of metrics, enter the name of the service. The metrics are filtered by the service you entered.

CloudWatch usage metrics

CloudWatch collects metrics that track the usage of some AWS resources. These metrics correspond to AWS service quotas. Tracking these metrics can help you proactively manage your quotas. For more information, see Visualizing your service quotas and setting alarms. Service quota usage metrics are in the `AWS/Usage` namespace and are collected every minute.

The metrics that can be published in this namespace include `CallCount`, `ResourceCount`, and `ThrottleCount`. These metrics are published with the dimensions `Resource`, `Service`, and `Type`. The `Resource` dimension specifies the name of the API operation being tracked. For example, the `CallCount` metric with the dimensions `"Service": "CloudWatch"`, `"Type": "API"` and `"Resource": "PutMetricData"` indicates the number of times the CloudWatch `PutMetricData` API operation has been called in your account.

The `CallCount` metric does not have a specified unit. The most useful statistic for the metric is `SUM`, which represents the total operation count for the 1-minute period.

Metrics

Metric	Description
`CallCount`	The number of specified operations performed in your account.

Dimensions

Dimension	Description
`Service`	The name of the AWS service containing the resource. For CloudWatch usage metrics, the value for this dimension is `CloudWatch` .
`Class`	The class of resource being tracked. CloudWatch API usage metrics use this dimension with a value of `None`.
`Type`	The type of resource being tracked. When the `Service` dimension is `CloudWatch` , the only valid value for `Type` is `API`.
`Resource`	The name of the API operation. Valid values include the following:

Dimension	Description
	DeleteAlarms ,DeleteDashboards ,DescribeAlarmHistory ,DescribeAlarms ,GetDashboard ,GetMetricData , GetMetricStatistics ,ListMetrics ,PutDashboard ,and PutMetricData

Amazon CloudWatch tutorials

The following scenarios illustrate how you can use Amazon CloudWatch. In the first scenario, you use the CloudWatch console to create a billing alarm that tracks your AWS usage and lets you know when you have exceeded a certain spending threshold. In the second scenario, you use the AWS Command Line Interface (AWS CLI) to publish a single metric for a hypothetical application named *GetStarted*.

Scenarios

- Monitor your estimated charges
- Publish metrics

Scenario: Monitor your estimated charges using CloudWatch

In this scenario, you create an Amazon CloudWatch alarm to monitor your estimated charges. When you enable the monitoring of estimated charges for your AWS account, the estimated charges are calculated and sent several times daily to CloudWatch as metric data.

Billing metric data is stored in the US East (N. Virginia) Region and reflects worldwide charges. This data includes the estimated charges for every service in AWS that you use, as well as the estimated overall total of your AWS charges.

You can choose to receive alerts by email when charges have exceeded a certain threshold. These alerts are triggered by CloudWatch and messages are sent using Amazon Simple Notification Service (Amazon SNS).

> **Note**
>
> For information about analyzing CloudWatch charges that you have already been billed for, see Analyzing, optimizing, and reducing CloudWatch costs.

Tasks

- Step 1: Enable billing alerts
- Step 2: Create a billing alarm

- Step 3: Check the alarm status
- Step 4: Edit a billing alarm
- Step 5: Delete a billing alarm

Step 1: Enable billing alerts

Before you can create an alarm for your estimated charges, you must enable billing alerts, so that you can monitor your estimated AWS charges and create an alarm using billing metric data. After you enable billing alerts, you cannot disable data collection, but you can delete any billing alarms that you created.

After you enable billing alerts for the first time, it takes about 15 minutes before you can view billing data and set billing alarms.

Requirements

- You must be signed in using root user credentials or as a user who has been given permission to view billing information.
- For consolidated billing accounts, billing data for each linked account can be found by logging in as the paying account. You can view billing data for total estimated charges and estimated charges by service for each linked account, in addition to the consolidated account.
- In a consolidated billing account, member linked account metrics are captured only if the payer account enables the **Receive Billing Alerts** preference. If you change which account is your management/payer account, you must enable the billing alerts in the new management/payer account.
- The account must not be part of the Amazon Partner Network (APN) because billing metrics are not published to CloudWatch for APN accounts. For more information, see AWS Partner Network.

To enable the monitoring of estimated charges

1. Open the AWS Billing and Cost Management console at https://console.aws.amazon.com/costmanagement/.
2. In the navigation pane, choose **Billing Preferences**.
3. By **Alert preferences** choose **Edit**.
4. Choose **Receive CloudWatch Billing Alerts**.
5. Choose **Save preferences**.

Step 2: Create a billing alarm

> **Important**
>
> Before you create a billing alarm, you must set your Region to US East (N. Virginia). Billing metric data is stored in this Region and represents worldwide charges. You also must enable billing alerts for your account or in the management/payer account (if you are using consolidated billing). For more information, see Step 1: Enable billing alerts.

In this procedure, you create an alarm that sends a notification when your estimated charges for AWS exceed a defined threshold.

To create a billing alarm using the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**. In the **Browse** tab, choose **Billing**, and then choose **Total Estimated Charge**.

   > **Note**
   >
   > If you don't see the **Billing/Total Estimated Charge** metric, enable billing alerts, and change your Region to US East (N. Virginia). For more information, see Enabling billing alerts.

5. Select the checkbox for the **EstimatedCharges** metric, and then choose **Select metric**.
6. For **Statistic**, choose **Maximum**.
7. For **Period**, choose **6 hours**.
8. For **Threshold type**, choose **Static**.
9. For **Whenever EstimatedCharges is . . .**, choose **Greater**.
10. For **than . . .**, define the value that you want to cause your alarm to trigger. For example, **200** USD.

    The **EstimatedCharges** metric values are only in US dollars (USD), and the currency conversion is provided by Amazon Services LLC. For more information, see What is AWS Billing?.

11. Choose **Additional Configuration** and do the following:

    - For **Datapoints to alarm**, specify **1 out of 1**.
    - For **Missing data treatment**, choose **Treat missing data as missing**.

12. Choose **Next**.
13. Under **Notification**, ensure that **In alarm** is selected. Then specify an Amazon SNS topic to be notified when your alarm is in the ALARM state. The Amazon SNS topic can include your email address so that you recieve email when the billing amount crosses the threshold that you specified.

    You can select an existing Amazon SNS topic, create a new Amazon SNS topic, or use a topic ARN to notify other account. If you want your alarm to send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

14. Choose **Next**.
15. Under **Name and description**, enter a name for your alarm.

    - (Optional) Enter a description of your alarm.

16. Choose **Next**.
17. Under **Preview and create**, make sure that your configuration is correct, and then choose **Create alarm**.

Step 3: Check the alarm status

Now, check the status of the billing alarm that you just created.

To check the alarm status

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Find the row in the table for your new alarm. Until the subscription is confirmed, it is shown as "Pending confirmation". After the subscription is confirmed, refresh the console to show the updated status.

Step 4: Edit a billing alarm

For example, you may want to increase the amount of money you spend with AWS each month from $200 to $400. You can edit your existing billing alarm and increase the monetary amount that must be exceeded before the alarm is triggered.

To edit a billing alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Select the checkbox next to the alarm and choose **Actions**, **Edit**.
5. For **than...**, specify the new amount that must be exceeded to trigger the alarm and send an email notification.
6. Choose **Save Changes**.

Step 5: Delete a billing alarm

If you no longer need your billing alarm, you can delete it.

To delete a billing alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Select the checkbox next to the alarm and choose **Actions**, **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

Scenario: Publish metrics to CloudWatch

In this scenario, you use the AWS Command Line Interface (AWS CLI) to publish a single metric for a hypothetical application named *GetStarted*. If you haven't already installed and configured the AWS CLI, see Getting Set Up with the AWS Command Line Interface in the *AWS Command Line Interface User Guide*.

Tasks

- Step 1: Define the data configuration
- Step 2: Add metrics to CloudWatch
- Step 3: Get statistics from CloudWatch
- Step 4: View graphs with the console

Step 1: Define the data configuration

In this scenario, you publish data points that track the request latency for the application. Choose names for your metric and namespace that make sense to you. For this example, name the metric *RequestLatency* and place all of the data points into the *GetStarted* namespace.

You publish several data points that collectively represent three hours of latency data. The raw data comprises 15 request latency readings distributed over three hours. Each reading is in milliseconds:

- Hour one: 87, 51, 125, 235
- Hour two: 121, 113, 189, 65, 89
- Hour three: 100, 47, 133, 98, 100, 328

You can publish data to CloudWatch as single data points or as an aggregated set of data points called a *statistic set*. You can aggregate metrics to a granularity as low as one minute. You can publish the aggregated data points to CloudWatch as a set of statistics with four predefined keys: `Sum`, `Minimum`, `Maximum`, and `SampleCount`.

You publish the data points from hour one as single data points. For the data from hours two and three, you aggregate the data points and publish a statistic set for each hour. The key values are shown in the following table.

Hour	Raw data	Sum	Minimum	Maximum	SampleCount
1	87				
1	51				

Hour	Raw data	Sum	Minimum	Maximum	SampleCount
1	125				
1	235				
2	121, 113, 189, 65, 89	577	65	189	5
3	100, 47, 133, 98, 100, 328	806	47	328	6

Step 2: Add metrics to CloudWatch

After you have defined your data configuration, you are ready to add data.

To publish data points to CloudWatch

1. At a command prompt, run the following put-metric-data commands to add data for the first hour. Replace the example timestamp with a timestamp that is two hours in the past, in Universal Coordinated Time (UTC).

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 87 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 51 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 125 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 235 --unit Milliseconds
```

2. Add data for the second hour, using a timestamp that is one hour later than the first hour.

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
```

```
--timestamp 2016-10-14T21:30:00Z --statistic-values
 Sum=577,Minimum=65,Maximum=189,SampleCount=5 --unit Milliseconds
```

3. Add data for the third hour, omitting the timestamp to default to the current time.

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--statistic-values Sum=806,Minimum=47,Maximum=328,SampleCount=6 --unit Milliseconds
```

Step 3: Get statistics from CloudWatch

Now that you have published metrics to CloudWatch, you can retrieve statistics based on those metrics using the get-metric-statistics command as follows. Be sure to specify `--start-time` and `--end-time` far enough in the past to cover the earliest timestamp that you published.

```
aws cloudwatch get-metric-statistics --namespace GetStarted --metric-name
 RequestLatency --statistics Average \
--start-time 2016-10-14T00:00:00Z --end-time 2016-10-15T00:00:00Z --period 60
```

The following is example output:

```
{
 "Datapoints": [],
 "Label": "Request:Latency"
}
```

Step 4: View graphs with the console

After you have published metrics to CloudWatch, you can use the CloudWatch console to view statistical graphs.

To view graphs of your statistics on the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the **Navigation** pane, choose **Metrics**.
3. On the **All metrics** tab, in the search box, type **RequestLatency** and press Enter.
4. Select the check box for the **RequestLatency** metric. A graph of the metric data is displayed in the upper pane.

For more information, see Graphing metrics.

FAQs on CloudWatch supported protocols

CloudWatch now supports for two additional protocols: AWS JSON 1.0 and Smithy RPC v2 CBOR. These protocols provide better performance than the AWS Query protocol that is currently utilized by the AWS SDKs and CLIs. AWS SDKs will prioritize the protocol that is the most performant for each language.

What is the AWS JSON protocol, and how does it differ from existing CloudWatch API requests and responses?

JSON is one of the most widely used and accepted wiring methods for communication between heterogeneous systems. CloudWatch uses JSON as a medium to communicate between an AWS SDK client (for example, Java, Python, Golang, JavaScript) and CloudWatch server. An HTTP request of an CloudWatch API operation accepts input in the form of JSON. The CloudWatch operation is executed and the response of execution is shared back to the SDK client in the form of JSON. Compared to AWS query, JSON is more efficient at transporting data between client and server.

- CloudWatch AWS JSON protocol acts as a mediator between CloudWatch client and server.
- The server doesn't understand the programming language in which the CloudWatch operation is created, but it understands the AWS JSON protocol.
- The CloudWatch AWS JSON protocol uses the serialization (convert object to JSON format) and deserialization (convert JSON format to object) between the CloudWatch client and server.

What is the Smithy RPC v2 CBOR protocol, and how does it differ from existing CloudWatch API requests and responses?

The Concise Binary Object Representation (CBOR) is a data format focused on efficiency and flexibility. Its key design goals include extremely small code size, compact message size, and version-free extensibility. Smithy RPC v2 CBOR, an Amazon-invented protocol, builds on these advantages to enable more efficient data transmission. RPC V2 CBOR implements binary encoding rather than the text encoding of JSON, reducing the size of payloads and the time spent on serialization.

- CloudWatch RPC v2 CBOR protocol acts as a mediator between CloudWatch client and server.

- The server doesn't understand the programming language in which the CloudWatch operation is created, but it understands the RPC v2 CBOR protocol.
- The CloudWatch RPC v2 CBOR protocol uses the serialization (convert object to CBOR format) and deserialization (convert CBOR format to object) between the CloudWatch client and server.

How do I get started with the newer protocols for CloudWatch?

The new protocols are now available in a public preview version of the SDKs. SDKs can be downloaded using the instructions below.

> **Note**
>
> The following specific issues are present in the preview version of the CloudWatch SDKs listed below. Using this preview SDK means these issues could affect your integration. We plan to address these issues before the final release.
>
> - Affecting all SDKs – The preview version removes trailing null values from lists. In the final release, these values will be properly serialized
> - Specific to Java SDK v1 – The preview version does not serialize empty lists. In the final release, empty lists will be properly serialized

SDK Client Protocol Support

Language	SDK client repository	SDK download link	SDK installation instructions	Protocol
C++	aws/aws-sdk-cpp	Link to download	Installation instructions	AWS JSON 1.0
Golang 2.x	aws/aws-sdk-go-v2	Link to download	Installation instructions	RPC v2 CBOR
Java 1.x	aws/aws-sdk-java	Link to download	Installation instructions	RPC v2 CBOR
Java 2.x	aws/aws-sdk-java-v2	Link to download	Installation instructions	RPC v2 CBOR

Language	SDK client repository	SDK download link	SDK installation instructions	Protocol
JavaScript v3.x	aws/aws-sdk-js-v3	Link to download	Installation instructions	AWS JSON 1.0
.NET	aws/aws-sdk-net	Link to download	Installation instructions	AWS JSON 1.0
PHP	aws/aws-sdk-php	Link to download	Installation instructions	AWS JSON 1.0

Rust	awslabs/aws-sdk-rust	Link to download	Installation instructions	RPC v2 CBOR
Swift	awslabs/aws-sdk-swift	Link to download	Installation instructions	RPC v2 CBOR
Kotlin	awslabs/aws-sdk-kotlin	Link to download	Installation instructions	RPC v2 CBOR

What are the risks of enabling these new protocols for my CloudWatch workloads?

If you are using a custom implementation of AWS SDK or a combination of custom clients and AWS SDK to interact with CloudWatch that generates AWS Query based (aka XML-based) responses, it may be incompatible with AWS JSON or CBOR protocol. If you encounter any issues, contact AWS Support.

What if I am already on the latest AWS SDK version, but my open sourced solution does not support JSON or CBOR?

You must change your SDK version to a previous version. See How do I get started with the newer protocols for CloudWatch? for how to get started with the newer protocols for CloudWatch and select a version lower than listed. If you change your AWS SDK to the previous version, your CloudWatch APIs will use the AWS query protocol.

What regions are supported for AWS JSON and CBOR protocols used in CloudWatch APIs

CloudWatch supports AWS JSON and CBOR protocol in all AWS regions where CloudWatch is available.

What latency improvements can I expect when upgrading to the specified AWS SDK versions for CloudWatch using the newer protocols?

Both JSON and CBOR provides between 50% to 80% latency improvement when compared to the AWS Query. CBOR is 50% faster for the client. Both protocols are 10-20% more efficient in network bandwidth usage.

Will AWS query protocol be deprecated?

AWS query protocol will continue to be supported. You can continue using AWS query protocol as long as your AWS SDK version is set any previous version other that what is listed in How do I get started with AWS JSON protocols for CloudWatch.

Where can I find more information about AWS JSON and Smithy RPC v2 CBOR protocols?

You can find more information about JSON protocol at AWS JSON 1.0 protocol in the Smithy documentation.

For more about CloudWatch API requests, see Making API Requests in the CloudWatch API Reference Guide.

Using CloudWatch with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS CLI	AWS CLI code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS Tools for PowerShell	AWS Tools for PowerShell code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples
AWS SDK for SAP ABAP	AWS SDK for SAP ABAP code examples
AWS SDK for Swift	AWS SDK for Swift code examples

For examples specific to CloudWatch, see Code examples for CloudWatch using AWS SDKs.

Example availability

Can't find what you need? Request a code example by using the **Provide feedback** link at the bottom of this page.

Code examples for CloudWatch using AWS SDKs

The following code examples show how to use CloudWatch with an AWS software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello CloudWatch

The following code examples show how to get started using CloudWatch.

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
using Amazon.CloudWatch;
using Amazon.CloudWatch.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;

namespace CloudWatchActions;
```

```
public static class HelloCloudWatch
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
 the Amazon CloudWatch service.
        // Use your AWS profile name, or leave it blank to use the default
 profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonCloudWatch>()
            ).Build();

        // Now the client is available for injection.
        var cloudWatchClient =
 host.Services.GetRequiredService<IAmazonCloudWatch>();

        // You can use await and any of the async methods to get a response.
        var metricNamespace = "AWS/Billing";
        var response = await cloudWatchClient.ListMetricsAsync(new
 ListMetricsRequest
        {

Hello CloudWatch

The following code examples show how to get started using CloudWatch.

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
using Amazon.CloudWatch;
using Amazon.CloudWatch.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;

namespace CloudWatchActions;

public static class HelloCloudWatch
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
 the Amazon CloudWatch service.
        // Use your AWS profile name, or leave it blank to use the default
 profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonCloudWatch>()
            ).Build();

        // Now the client is available for injection.
        var cloudWatchClient =
 host.Services.GetRequiredService<IAmazonCloudWatch>();

        // You can use await and any of the async methods to get a response.
        var metricNamespace = "AWS/Billing";
        var response = await cloudWatchClient.ListMetricsAsync(new
 ListMetricsRequest
        {
            Namespace = metricNamespace
        });
```

```
        Console.WriteLine($"Hello Amazon CloudWatch! Following are some metrics
 available in the {metricNamespace} namespace:");
        Console.WriteLine();
        if (response.Metrics != null)
        {
            foreach (var metric in response.Metrics.Take(5))
            {
                Console.WriteLine($"\tMetric: {metric.MetricName}");
                Console.WriteLine($"\tNamespace: {metric.Namespace}");
                Console.WriteLine(
                    $"\tDimensions: {string.Join(", ", metric.Dimensions.Select(m
 => $"{m.Name}:{m.Value}"))}");
                Console.WriteLine();
            }
        }
    }
}
```

- For API details, see ListMetrics in *AWS SDK for .NET API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Learn core operations for CloudWatch using an AWS SDK

The following code examples show how to:

- List CloudWatch namespaces and metrics.
- Get statistics for a metric and for estimated billing.
- Create and update a dashboard.
- Create and add data to a metric.
- Create and trigger an alarm, then view alarm history.
- Add an anomaly detector.
- Get a metric image, then clean up resources.

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
public class CloudWatchScenario
{
    /*
    Before running this .NET code example, set up your development environment,
 including your credentials.

    To enable billing metrics and statistics for this example, make sure billing
 alerts are enabled for your account:
    https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics

    This .NET example performs the following tasks:
        1. List and select a CloudWatch namespace.
        2. List and select a CloudWatch metric.
        3. Get statistics for a CloudWatch metric.
        4. Get estimated billing statistics for the last week.
        5. Create a new CloudWatch dashboard with two metrics.
        6. List current CloudWatch dashboards.
        7. Create a CloudWatch custom metric and add metric data.
        8. Add the custom metric to the dashboard.
        9. Create a CloudWatch alarm for the custom metric.
       10. Describe current CloudWatch alarms.
       11. Get recent data for the custom metric.
       12. Add data to the custom metric to trigger the alarm.
       13. Wait for an alarm state.
       14. Get history for the CloudWatch alarm.
       15. Add an anomaly detector.
       16. Describe current anomaly detectors.
       17. Get and display a metric image.
       18. Clean up resources.
    */

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
 * To enable billing metrics and statistics for this example, make sure billing
 * alerts are enabled for your account:
 * https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics
 *
 * This Java code example performs the following tasks:
 *
 * 1. List available namespaces from Amazon CloudWatch.
 * 2. List available metrics within the selected Namespace.
 * 3. Get statistics for the selected metric over the last day.
 * 4. Get CloudWatch estimated billing for the last week.
 * 5. Create a new CloudWatch dashboard with metrics.
 * 6. List dashboards using a paginator.
 * 7. Create a new custom metric by adding data for it.
```

```
 * 8. Add the custom metric to the dashboard.
 * 9. Create an alarm for the custom metric.
 * 10. Describe current alarms.
 * 11. Get current data for the new custom metric.
 * 12. Push data into the custom metric to trigger the alarm.
 * 13. Check the alarm state using the action DescribeAlarmsForMetric.
 * 14. Get alarm history for the new alarm.
 * 15. Add an anomaly detector for the custom metric.
 * 16. Describe current anomaly detectors.
 * 17. Get a metric image for the custom metric.
 * 18. Clean up the Amazon CloudWatch resources.

            Amazon CloudWatch is a comprehensive monitoring and observability
service
            provided by Amazon Web Services (AWS). It is designed to help you
monitor your
            AWS resources, applications, and services, as well as on-premises
resources,
            in real-time.

            CloudWatch collects and tracks various types of data, including
metrics,
            logs, and events, from your AWS and on-premises resources. It allows
you to set
            alarms and automatically respond to changes in your environment,
            enabling you to quickly identify and address issues before they
impact your
            applications or services.

            With CloudWatch, you can gain visibility into your entire
infrastructure, from the cloud
            to the edge, and use this information to make informed decisions and
optimize your
            resource utilization.

            This scenario guides you through how to perform Amazon CloudWatch
tasks by using the
            AWS SDK for Java v2. Let's get started...

            An anomaly detector is a feature that automatically detects unusual
patterns or deviations in your
            monitored metrics. It uses machine learning algorithms to analyze the
historical behavior
            of your metrics and establish a baseline.

            The anomaly detector then compares the current metric values against
this baseline and
            identifies any anomalies or outliers that may indicate potential
issues or unexpected changes
            in your system's performance or behavior.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario demonstrating CloudWatch features.

```
/**
 Before running this Kotlin code example, set up your development environment,
 including your credentials.

 For more information, see the following documentation topic:
 https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

 To enable billing metrics and statistics for this example, make sure billing
 alerts are enabled for your account:
 https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics

 This Kotlin code example performs the following tasks:

 1. List available namespaces from Amazon CloudWatch. Select a namespace from the
 list.
 2. List available metrics within the selected namespace.
 3. Get statistics for the selected metric over the last day.
 4. Get CloudWatch estimated billing for the last week.
 5. Create a new CloudWatch dashboard with metrics.
 6. List dashboards using a paginator.
 7. Create a new custom metric by adding data for it.
 8. Add the custom metric to the dashboard.
 9. Create an alarm for the custom metric.
 10. Describe current alarms.
 11. Get current data for the new custom metric.
 12. Push data into the custom metric to trigger the alarm.
 13. Check the alarm state using the action DescribeAlarmsForMetric.
 14. Get alarm history for the new alarm.
 15. Add an anomaly detector for the custom metric.
```

```
 16. Describe current anomaly detectors.
 17. Get a metric image for the custom metric.
 18. Clean up the Amazon CloudWatch resources.

Actions for CloudWatch using AWS SDKs

The following code examples demonstrate how to perform individual CloudWatch actions with AWS SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the CloudWatch API and are code excerpts from larger programs that must be run in context. You can see actions in context in Scenarios for CloudWatch using AWS SDKs .

The following examples include only the most commonly used actions. For a complete list, see the Amazon CloudWatch API Reference.

Examples

- Use DeleteAlarms with an AWS SDK or CLI
- Use DeleteAnomalyDetector with an AWS SDK or CLI
- Use DeleteDashboards with an AWS SDK or CLI
- Use DescribeAlarmHistory with an AWS SDK or CLI
- Use DescribeAlarms with an AWS SDK or CLI
- Use DescribeAlarmsForMetric with an AWS SDK or CLI
- Use DescribeAnomalyDetectors with an AWS SDK or CLI
- Use DisableAlarmActions with an AWS SDK or CLI
- Use EnableAlarmActions with an AWS SDK or CLI
- Use GetDashboard with an AWS SDK or CLI
- Use GetMetricData with an AWS SDK or CLI
- Use GetMetricStatistics with an AWS SDK or CLI
- Use GetMetricWidgetImage with an AWS SDK or CLI
- Use ListDashboards with an AWS SDK or CLI
- Use ListMetrics with an AWS SDK or CLI
- Use PutAnomalyDetector with an AWS SDK or CLI
- Use PutDashboard with an AWS SDK or CLI
- Use PutMetricAlarm with an AWS SDK or CLI
- Use PutMetricData with an AWS SDK or CLI

Use `DeleteAlarms` with an AWS SDK or CLI

The following code examples show how to use `DeleteAlarms`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Get started with alarms
- Manage metrics and alarms

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/// <summary>
/// Delete a list of alarms from CloudWatch.
/// </summary>
/// <param name="alarmNames">A list of names of alarms to delete.</param>
/// <returns>True if successful.</returns>
public async Task<bool> DeleteAlarms(List<string> alarmNames)
{
    var deleteAlarmsResult = await _amazonCloudWatch.DeleteAlarmsAsync(
        new DeleteAlarmsRequest()
        {
            AlarmNames = alarmNames
        });

    return deleteAlarmsResult.HttpStatusCode == HttpStatusCode.OK;
}
```

- For API details, see DeleteAlarms in *AWS SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/DeleteAlarmsRequest.h>
#include <iostream>
```

Delete the alarm.

```
        Aws::CloudWatch::CloudWatchClient cw;
        Aws::CloudWatch::Model::DeleteAlarmsRequest request;
        request.AddAlarmNames(alarm_name);

        auto outcome = cw.DeleteAlarms(request);
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to delete CloudWatch alarm:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
        else
        {
            std::cout << "Successfully deleted CloudWatch alarm " << alarm_name
                << std::endl;
        }
```

- For API details, see DeleteAlarms in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To delete an alarm

The following example uses the `delete-alarms` command to delete the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch delete-alarms --alarm-names myalarm
```

Output:

```
This command returns to the prompt if successful.
```

- For API details, see DeleteAlarms in *AWS CLI Command Reference*.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Deletes a CloudWatch alarm.
    *
    * @param alarmName the name of the alarm to be deleted
    * @return a {@link CompletableFuture} representing the asynchronous
operation to delete the alarm
    * the {@link DeleteAlarmsResponse} is returned when the operation completes
successfully,
    * or a {@link RuntimeException} is thrown if the operation fails
    */
   public CompletableFuture<DeleteAlarmsResponse> deleteCWAlarmAsync(String
alarmName) {
       DeleteAlarmsRequest request = DeleteAlarmsRequest.builder()
           .alarmNames(alarmName)
           .build();

       return getAsyncClient().deleteAlarms(request)
           .whenComplete((response, exception) -> {
               if (exception != null) {
                   throw new RuntimeException("Failed to delete the alarm:{} " +
alarmName, exception);
               } else {
                   logger.info("Successfully deleted alarm {} ", alarmName);
               }
           });
   }
```

- For API details, see DeleteAlarms in *AWS SDK for Java 2.x API Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { DeleteAlarmsCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  const command = new DeleteAlarmsCommand({
    AlarmNames: [process.env.CLOUDWATCH_ALARM_NAME], // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see DeleteAlarms in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

var params = {
  AlarmNames: ["Web_Server_CPU_Utilization"],
};

cw.deleteAlarms(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see DeleteAlarms in *AWS SDK for JavaScript API Reference*.

Kotlin

SDK for Kotlin

> **Note**
>

    ENDTRY.
```

- For API details, see DeleteAlarms in *AWS SDK for SAP ABAP API reference*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DeleteAnomalyDetector` with an AWS SDK or CLI

The following code examples show how to use `DeleteAnomalyDetector`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Delete a single metric anomaly detector.
    /// </summary>
    /// <param name="anomalyDetector">The anomaly detector to delete.</param>
    /// <returns>True if successful.</returns>
```

```
    public async Task<bool> DeleteAnomalyDetector(SingleMetricAnomalyDetector
anomalyDetector)
    {
        var deleteAnomalyDetectorResponse = await
_amazonCloudWatch.DeleteAnomalyDetectorAsync(
            new DeleteAnomalyDetectorRequest()
            {
                SingleMetricAnomalyDetector = anomalyDetector
            });

        return deleteAnomalyDetectorResponse.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see DeleteAnomalyDetector in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To delete a specified anomaly detection model

The following `delete-anomaly-detector` example deletes an anomaly detector model in the specified account.

```
aws cloudwatch delete-anomaly-detector \
    --namespace AWS/Logs \
    --metric-name IncomingBytes \
    --stat SampleCount
```

This command produces no output.

For more information, see Deleting an anomaly detection model in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteAnomalyDetector in *AWS CLI Command Reference*.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Deletes an Anomaly Detector.
    *
    * @param fileName the name of the file containing the Anomaly Detector
configuration
    * @return a CompletableFuture that represents the asynchronous deletion of
the Anomaly Detector
    */

Use `DeleteDashboards` with an AWS SDK or CLI

The following code examples show how to use `DeleteDashboards`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Delete a list of CloudWatch dashboards.
    /// </summary>
    /// <param name="dashboardNames">List of dashboard names to delete.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> DeleteDashboards(List<string> dashboardNames)
    {
        var deleteDashboardsResponse = await
_amazonCloudWatch.DeleteDashboardsAsync(
            new DeleteDashboardsRequest()
            {
                DashboardNames = dashboardNames
            });

        return deleteDashboardsResponse.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see DeleteDashboards in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To delete specified dashboards

The following `delete-dashboards` example deletes two dashboards named `Dashboard-A` and `Dashboard-B` in the specified account.

```
aws cloudwatch delete-dashboards \
    --dashboard-names Dashboard-A Dashboard-B
```

This command produces no output.

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteDashboards in *AWS CLI Command Reference*.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Deletes the specified dashboard.
    *
    * @param dashboardName the name of the dashboard to be deleted
    * @return a {@link CompletableFuture} representing the asynchronous
operation of deleting the dashboard
    * @throws RuntimeException if the dashboard deletion fails
    */
   public CompletableFuture<DeleteDashboardsResponse>
deleteDashboardAsync(String dashboardName) {
       DeleteDashboardsRequest dashboardsRequest =
DeleteDashboardsRequest.builder()
           .dashboardNames(dashboardName)
           .build();

       return getAsyncClient().deleteDashboards(dashboardsRequest)
           .whenComplete((response, exception) -> {
               if (exception != null) {
                   throw new RuntimeException("Failed to delete the dashboard: "
+ dashboardName, exception);
               } else {
                   logger.info("{} was successfully deleted.", dashboardName);
               }
           });
   }
```

- For API details, see DeleteDashboards in *AWS SDK for Java 2.x API Reference*.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
suspend fun deleteDashboard(dashboardName: String) {
    val dashboardsRequest =
        DeleteDashboardsRequest {
            dashboardNames = listOf(dashboardName)
        }
    CloudWatchClient.fromEnvironment { region = "us-east-1" }.use { cwClient ->
        cwClient.deleteDashboards(dashboardsRequest)
        println("$dashboardName was successfully deleted.")
    }
}
```

- For API details, see DeleteDashboards in *AWS SDK for Kotlin API reference*.

PowerShell

Tools for PowerShell V4

Example 1: Deletes the specified dashboard, promoting for confirmation before proceeding. To bypass confirmation add the -Force switch to the command.

```
Remove-CWDashboard -DashboardName Dashboard1
```

- For API details, see DeleteDashboards in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Deletes the specified dashboard, promoting for confirmation before proceeding. To bypass confirmation add the -Force switch to the command.

```
Remove-CWDashboard -DashboardName Dashboard1
```

- For API details, see DeleteDashboards in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DescribeAlarmHistory` with an AWS SDK or CLI

The following code examples show how to use `DescribeAlarmHistory`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

SDK for .NET

```
    /// <summary>
    /// Describe the history of an alarm for a number of days in the past.
    /// </summary>
    /// <param name="alarmName">The name of the alarm.</param>
    /// <param name="historyDays">The number of days in the past.</param>
    /// <returns>The list of alarm history data.</returns>
    public async Task<List<AlarmHistoryItem>> DescribeAlarmHistory(string
alarmName, int historyDays)
```

```
    {
        List<AlarmHistoryItem> alarmHistory = new List<AlarmHistoryItem>();
        var paginatedAlarmHistory =
 _amazonCloudWatch.Paginators.DescribeAlarmHistory(
            new DescribeAlarmHistoryRequest()
            {
                AlarmName = alarmName,
                EndDateUtc = DateTime.UtcNow,
                HistoryItemType = HistoryItemType.StateUpdate,
                StartDateUtc = DateTime.UtcNow.AddDays(-historyDays)
            });

        await foreach (var data in paginatedAlarmHistory.AlarmHistoryItems)
        {
            alarmHistory.Add(data);
        }
        return alarmHistory;
    }
```

- For API details, see DescribeAlarmHistory in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To retrieve history for an alarm

The following example uses the `describe-alarm-history` command to retrieve history for the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch describe-alarm-history --alarm-name "myalarm" --history-item-
type StateUpdate
```

Output:

```
{
    "AlarmHistoryItems": [
        {
            "Timestamp": "2014-04-09T18:59:06.442Z",
            "HistoryItemType": "StateUpdate",
            "AlarmName": "myalarm",
```

```
            "HistoryData": "{\"version\":\"1.0\",\"oldState\":{\"stateValue
\":\"ALARM\",\"stateReason\":\"testing purposes\"},\"newState\":{\"stateValue
\":\"OK\",\"stateReason\":\"Threshold Crossed: 2 datapoints were not
 greater than the threshold (70.0). The most recent datapoints: [38.958,
 40.292].\",\"stateReasonData\":{\"version\":\"1.0\",\"queryDate\":
\"2014-04-09T18:59:06.419+0000\",\"startDate\":\"2014-04-09T18:44:00.000+0000\",
\"statistic\":\"Average\",\"period\":300,\"recentDatapoints\":[38.958,40.292],
\"threshold\":70.0}}}",
            "HistorySummary": "Alarm updated from ALARM to OK"
        },
        {
            "Timestamp": "2014-04-09T18:59:05.805Z",
            "HistoryItemType": "StateUpdate",
            "AlarmName": "myalarm",
            "HistoryData": "{\"version\":\"1.0\",\"oldState\":{\"stateValue
\":\"OK\",\"stateReason\":\"Threshold Crossed: 2 datapoints were
 not greater than the threshold (70.0). The most recent datapoints:
 [38.839999999999996, 39.714].\",\"stateReasonData\":{\"version\":
\"1.0\",\"queryDate\":\"2014-03-11T22:45:41.569+0000\",\"startDate\":
\"2014-03-11T22:30:00.000+0000\",\"statistic\":\"Average\",\"period\":300,

PowerShell

Tools for PowerShell V4

Example 1: Returns all the alarms including Composite and Metric Alarms from CloudWatch.

```
Get-CWAlarm -MaxRecords 1
```

Output:

```
CompositeAlarms MetricAlarms         NextToken
--------------- ------------         ---------
                {MetricAlarms-01}    NextToken-01
                {MetricAlarms-02}    NextToken-02
                {MetricAlarms-03}    NextToken-03
```

Example 2: Returns only the composite alarms data from CloudWatch after setting -AlarmType parameter to CompositeAlarms.

```
Get-CWAlarm -AlarmType 'CompositeAlarms'
```

Output:

```
CompositeAlarms        MetricAlarms NextToken
---------------        ------------ ---------
{CompositeAlarms-01}
{CompositeAlarms-02}
{CompositeAlarms-03}
```

        }
```

- For API details, see DescribeAlarmsForMetric in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To display information about alarms associated with a metric

The following example uses the `describe-alarms-for-metric` command to display information about any alarms associated with the Amazon EC2 CPUUtilization metric and the instance with the ID i-0c986c72.:

```
aws cloudwatch describe-alarms-for-metric --metric-name CPUUtilization --
namespace AWS/EC2 --dimensions Name=InstanceId,Value=i-0c986c72
```

Output:

```
{
    "MetricAlarms": [
        {
            "EvaluationPeriods": 10,
            "AlarmArn": "arn:aws:cloudwatch:us-

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { DescribeAlarmsCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  const command = new DescribeAlarmsCommand({
    AlarmNames: [process.env.CLOUDWATCH_ALARM_NAME], // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Disable the actions for a list of alarms from CloudWatch.
    /// </summary>
    /// <param name="alarmNames">A list of names of alarms.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> DisableAlarmActions(List<string> alarmNames)
    {
        var disableAlarmActionsResult = await
_amazonCloudWatch.DisableAlarmActionsAsync(
            new DisableAlarmActionsRequest()
            {
                AlarmNames = alarmNames
            });

        return disableAlarmActionsResult.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see DisableAlarmActions in *AWS SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/DisableAlarmActionsRequest.h>
#include <iostream>
```

Disable the alarm actions.

```
        Aws::CloudWatch::CloudWatchClient cw;

        Aws::CloudWatch::Model::DisableAlarmActionsRequest
 disableAlarmActionsRequest;
        disableAlarmActionsRequest.AddAlarmNames(alarm_name);

        auto disableAlarmActionsOutcome =
 cw.DisableAlarmActions(disableAlarmActionsRequest);
        if (!disableAlarmActionsOutcome.IsSuccess())
        {
            std::cout << "Failed to disable actions for alarm " << alarm_name <<
                ": " << disableAlarmActionsOutcome.GetError().GetMessage() <<
                std::endl;
        }
        else
        {
            std::cout << "Successfully disabled actions for alarm " <<
```

```
                alarm_name << std::endl;
        }
```

- For API details, see DisableAlarmActions in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To disable actions for an alarm

The following example uses the `disable-alarm-actions` command to disable all actions for the alarm named myalarm.:

```
aws cloudwatch disable-alarm-actions --alarm-names myalarm
```

This command returns to the prompt if successful.

- For API details, see DisableAlarmActions in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { EnableAlarmActionsCommand } from "@aws-sdk/client-cloudwatch";
```

```
import { client } from "../libs/client.js";

const run = async () => {
  const command = new EnableAlarmActionsCommand({
    AlarmNames: [process.env.CLOUDWATCH_ALARM_NAME], // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see EnableAlarmActions in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });
```

```
// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

var params = {
  AlarmName: "Web_Server_CPU_Utilization",
  ComparisonOperator: "GreaterThanThreshold",
  EvaluationPeriods: 1,
  MetricName: "CPUUtilization",
  Namespace: "AWS/EC2",
  Period: 60,
  Statistic: "Average",
  Threshold: 70.0,
  ActionsEnabled: true,
  AlarmActions: ["ACTION_ARN"],
  AlarmDescription: "Alarm when server CPU exceeds 70%",
  Dimensions: [
    {
      Name: "InstanceId",
      Value: "INSTANCE_ID",
    },
  ],
  Unit: "Percent",
};

cw.putMetricAlarm(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Alarm action added", data);
    var paramsEnableAlarmAction = {
      AlarmNames: [params.AlarmName],
    };
    cw.enableAlarmActions(paramsEnableAlarmAction, function (err, data) {
      if (err) {
        console.log("Error", err);
      } else {
        console.log("Alarm action enabled", data);
      }
    });
  }
});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see EnableAlarmActions in *AWS SDK for JavaScript API Reference*.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
suspend fun enableActions(alarm: String) {
    val request =
        EnableAlarmActionsRequest {
            alarmNames = listOf(alarm)
        }

    CloudWatchClient.fromEnvironment { region = "us-east-1" }.use { cwClient ->
        cwClient.enableAlarmActions(request)
        println("Successfully enabled actions on alarm $alarm")
    }
}
```

Use `GetDashboard` with an AWS SDK or CLI

The following code examples show how to use `GetDashboard`.

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Get information on a dashboard.
    /// </summary>
    /// <param name="dashboardName">The name of the dashboard.</param>
    /// <returns>A JSON object with dashboard information.</returns>
    public async Task<string> GetDashboard(string dashboardName)
    {
        var dashboardResponse = await _amazonCloudWatch.GetDashboardAsync(
            new GetDashboardRequest()
            {
                DashboardName = dashboardName
            });

        return dashboardResponse.DashboardBody;
    }
```

- For API details, see GetDashboard in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To retrieve information about a Dashboard

The following `get-dashboard` example displays information about the dashboard named `Dashboard-A` in the specified account.

```
aws cloudwatch get-dashboard \
    --dashboard-name Dashboard-A
```

Output:

```
{
    "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/Dashboard-A",
    "DashboardBody": "{\"widgets\":[{\"type\":\"metric\",\"x\":0,\"y\":0,\"width
\":6,\"height\":6,\"properties\":{\"view\":\"timeSeries\",\"stacked\":false,
\"metrics\":[[\"AWS/EC2\",\"NetworkIn\",\"InstanceId\",\"i-0131f062232ade043\"],
[\".\",\"NetworkOut\",\".\",\".\"]],\"region\":\"us-east-1\"}}]}",
    "DashboardName": "Dashboard-A"
}
```

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see GetDashboard in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: Returns the arn the body of the specified dashboard.

```
Get-CWDashboard -DashboardName Dashboard1
```

Output:

```
DashboardArn                                            DashboardBody
------------                                            -------------
arn:aws:cloudwatch::123456789012:dashboard/Dashboard1 {...
```

- For API details, see GetDashboard in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Returns the arn the body of the specified dashboard.

```
Get-CWDashboard -DashboardName Dashboard1
```

Output:

```
DashboardArn                                            DashboardBody
------------                                            -------------
```

```
arn:aws:cloudwatch::123456789012:dashboard/Dashboard1 {...
```

- For API details, see GetDashboard in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Get data for CloudWatch metrics.
    /// </summary>
    /// <param name="minutesOfData">The number of minutes of data to include.</
param>
    /// <param name="useDescendingTime">True to return the data descending by
 time.</param>
    /// <param name="endDateUtc">The end date for the data, in UTC.</param>
    /// <param name="maxDataPoints">The maximum data points to include.</param>
    /// <param name="dataQueries">Optional data queries to include.</param>
    /// <returns>A list of the requested metric data.</returns>
    public async Task<List<MetricDataResult>> GetMetricData(int minutesOfData,
 bool useDescendingTime, DateTime? endDateUtc = null,
```

```
        int maxDataPoints = 0, List<MetricDataQuery>? dataQueries = null)
    {
        var metricData = new List<MetricDataResult>();
        // If no end time is provided, use the current time for the end time.
        endDateUtc ??= DateTime.UtcNow;
        var timeZoneOffset =
 TimeZoneInfo.Local.GetUtcOffset(endDateUtc.Value.ToLocalTime());
        var startTimeUtc = endDateUtc.Value.AddMinutes(-minutesOfData);
        // The timezone string should be in the format +0000, so use the timezone
 offset to format it correctly.
        var timeZoneString = $"{timeZoneOffset.Hours:D2}
{timeZoneOffset.Minutes:D2}";
        var paginatedMetricData = _amazonCloudWatch.Paginators.GetMetricData(
            new GetMetricDataRequest()
            {
                StartTimeUtc = startTimeUtc,
                EndTimeUtc = endDateUtc.Value,
                LabelOptions = new LabelOptions { Timezone = timeZoneString },
                ScanBy = useDescendingTime ? ScanBy.TimestampDescending :
 ScanBy.TimestampAscending,
                MaxDatapoints = maxDataPoints,
                MetricDataQueries = dataQueries,
            });

        await foreach (var data in paginatedMetricData.MetricDataResults)
        {
            metricData.Add(data);
        }
        return metricData;
    }
```

- For API details, see GetMetricData in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

Example 1: To get the Average Total IOPS for the specified EC2 using math expression

The following `get-metric-data` example retrieves CloudWatch metric values for the EC2 instance with InstanceID `i-abcdef` using metric math exprssion that combines `EBSReadOps` and `EBSWriteOps` metrics.

```
aws cloudwatch get-metric-data \
    --metric-data-queries file://file.json \
    --start-time 2024-09-29T22:10:00Z \
    --end-time 2024-09-29T22:15:00Z
```

Contents of `file.json`:

```
[
    {
        "Id": "m3",
        "Expression": "(m1+m2)/300",
        "Label": "Avg Total IOPS"
    },
    {
        "Id": "m1",
        "MetricStat": {
            "Metric": {
                "Namespace": "AWS/EC2",
                "MetricName": "EBSReadOps",
                "Dimensions": [
                    {
                        "Name": "InstanceId",
                        "Value": "i-abcdef"
                    }
                ]
            },
            "Period": 300,
            "Stat": "Sum",
            "Unit": "Count"
        },
        "ReturnData": false
    },
    {
        "Id": "m2",
        "MetricStat": {
            "Metric": {
                "Namespace": "AWS/EC2",
                "MetricName": "EBSWriteOps",
                "Dimensions": [
                    {
                        "Name": "InstanceId",
                        "Value": "i-abcdef"
                    }
```

```
                ]
            },
            "Period": 300,
            "Stat": "Sum",
            "Unit": "Count"
        },
        "ReturnData": false
    }
]
```

Output:

```
{
    "MetricDataResults": [
        {
            "Id": "m3",
            "Label": "Avg Total IOPS",
            "Timestamps": [
                "2024-09-29T22:10:00+00:00"
            ],
            "Values": [
                96.85
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

Example 2: To monitor the estimated AWS charges using CloudWatch billing metrics

The following `get-metric-data` example retrieves `EstimatedCharges` CloudWatch metric from AWS/Billing namespace.

```
aws cloudwatch get-metric-data \
    --metric-data-queries '[{"Id":"m1","MetricStat":{"Metric":
{"Namespace":"AWS/Billing","MetricName":"EstimatedCharges","Dimensions":
[{"Name":"Currency","Value":"USD"}]},"Period":21600,"Stat":"Maximum"}}]' \
    --start-time 2024-09-26T12:00:00Z \
    --end-time 2024-09-26T18:00:00Z \
    --region us-east-1
```

Output:

```
{
    "MetricDataResults": [
        {
            "Id": "m1",
            "Label": "EstimatedCharges",
            "Timestamps": [
                "2024-09-26T12:00:00+00:00"
            ],
            "Values": [
                542.38
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

CLI

AWS CLI

To get the CPU utilization per EC2 instance

The following example uses the `get-metric-statistics` command to get the CPU utilization for an EC2 instance with the ID i-abcdef.

```
aws cloudwatch get-metric-statistics --metric-name CPUUtilization --start-
time 2014-04-08T23:18:00Z --end-time 2014-04-09T23:18:00Z --period 3600 --
```

```
namespace AWS/EC2 --statistics Maximum --dimensions Name=InstanceId,Value=i-
abcdef
```

Output:

```
{
    "Datapoints": [
        {
            "Timestamp": "2014-04-09T11:18:00Z",
            "Maximum": 44.79,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T20:18:00Z",
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T19:18:00Z",
            "Maximum": 50.85,

        },
        {
            "Timestamp": "2014-04-09T01:18:00Z",
            "Maximum": 49.18,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

Specifying multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple

dimensions are separated by a space. If a single metric includes multiple dimensions, you must specify a value for every defined dimension.

For more examples using the `get-metric-statistics` command, see Get Statistics for a Metric in the *Amazon CloudWatch Developer Guide*.

```
aws cloudwatch get-metric-statistics --metric-name Buffers --
namespace MyNameSpace --dimensions Name=InstanceID,Value=i-
abcdef Name=InstanceType,Value=m1.small --start-time 2016-10-15T04:00:00Z --end-
time 2016-10-19T07:00:00Z --statistics Average --period 60
```

- For API details, see GetMetricStatistics in *AWS CLI Command Reference*.

Python

SDK for Python (Boto3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
class CloudWatchWrapper:
    """Encapsulates Amazon CloudWatch functions."""

    def __init__(self, cloudwatch_resource):
        """
        :param cloudwatch_resource: A Boto3 CloudWatch resource.
        """
        self.cloudwatch_resource = cloudwatch_resource

    def get_metric_statistics(self, namespace, name, start, end, period,
 stat_types):
        """
        Gets statistics for a metric within a specified time span. Metrics are
 grouped
        into the specified period.

        :param namespace: The namespace of the metric.
        :param name: The name of the metric.
        :param start: The UTC start time of the time span to retrieve.
        :param end: The UTC end time of the time span to retrieve.
```

```
        :param period: The period, in seconds, in which to group metrics. The
period
                       must match the granularity of the metric, which depends on
                       the metric's age. For example, metrics that are older than
                       three hours have a one-minute granularity, so the period
must
                       be at least 60 and must be a multiple of 60.
        :param stat_types: The type of statistics to retrieve, such as average
value
                           or maximum value.
        :return: The retrieved statistics for the metric.

CLI

AWS CLI

To retrieve a snapshot graph of CPUUtilization

The following `get-metric-widget-image` example retrieves snapshot graph for the metric `CPUUtilization` of the EC2 instance with the ID `i-abcde` and saves the retrieved image as a file named "image.png" on your local machine.

```
aws cloudwatch get-metric-widget-image \
    --metric-widget '{"metrics":[["AWS/EC2","CPUUtilization","InstanceId","i-
abcde"]]}' \
    --output-format png \
```

```
    --output text | base64 --decode > image.png
```

This command produces no output.

- For API details, see GetMetricWidgetImage in *AWS CLI Command Reference*.

Use `ListDashboards` with an AWS SDK or CLI

The following code examples show how to use `ListDashboards`.

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/// <summary>
/// Get a list of dashboards.
/// </summary>
/// <returns>A list of DashboardEntry objects.</returns>
public async Task<List<DashboardEntry>> ListDashboards()
{
    var results = new List<DashboardEntry>();
    var paginateDashboards = _amazonCloudWatch.Paginators.ListDashboards(
        new ListDashboardsRequest());
    // Get the entire list using the paginator.
    await foreach (var data in paginateDashboards.DashboardEntries)
    {
        results.Add(data);
    }

    return results;
}
```

- For API details, see ListDashboards in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To retrieve a list of Dashboards

The following `list-dashboards` example lists all the Dashboards in the specified account.

```
aws cloudwatch list-dashboards
```

Output:

```
{
    "DashboardEntries": [
        {
            "DashboardName": "Dashboard-A",
            "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/
Dashboard-A",
            "LastModified": "2024-10-11T18:40:11+00:00",
            "Size": 271
        },
        {
            "DashboardName": "Dashboard-B",
            "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/
Dashboard-B",
            "LastModified": "2024-10-11T18:44:41+00:00",
            "Size": 522
        }
    ]
}
```

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see ListDashboards in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: Returns the collection of dashboards for your account.

```
Get-CWDashboardList
```

Output:

```
DashboardArn DashboardName LastModified        Size
------------ ------------- ------------        ----
arn:...      Dashboard1    7/6/2017 8:14:15 PM 252
```

Example 2: Returns the collection of dashboards for your account whose names start with the prefix 'dev'.

```
Get-CWDashboardList -DashboardNamePrefix dev
```

- For API details, see ListDashboards in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Returns the collection of dashboards for your account.

```
Get-CWDashboardList
```

Output:

```
DashboardArn DashboardName LastModified        Size
------------ ------------- ------------        ----
arn:...      Dashboard1    7/6/2017 8:14:15 PM 252
```

Example 2: Returns the collection of dashboards for your account whose names start with the prefix 'dev'.

```
Get-CWDashboardList -DashboardNamePrefix dev
```

- For API details, see ListDashboards in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `ListMetrics` with an AWS SDK or CLI

The following code examples show how to use `ListMetrics`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics

- Manage metrics and alarms

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /// <summary>
   /// List metrics available, optionally within a namespace.
   /// </summary>
   /// <param name="metricNamespace">Optional CloudWatch namespace to use when
listing metrics.</param>

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import {
  CloudWatchServiceException,
  ListMetricsCommand,
} from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

export const main = async () => {
  // Use the AWS console to see available namespaces and metric names. Custom
 metrics can also be created.
  // https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
viewing_metrics_with_cloudwatch.html
  const command = new ListMetricsCommand({
    Dimensions: [
      {
```

```
        Name: "LogGroupName",
      },
    ],
    MetricName: "IncomingLogEvents",
    Namespace: "AWS/Logs",
  });

  try {
    const response = await client.send(command);
    console.log(`Metrics count: ${response.Metrics?.length}`);
    return response;
  } catch (caught) {
    if (caught instanceof CloudWatchServiceException) {
      console.error(`Error from CloudWatch. ${caught.name}: ${caught.message}`);
    } else {
      throw caught;
    }
  }
};
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see ListMetrics in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
```

```
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

var params = {
  Dimensions: [
    {
      Name: "LogGroupName" /* required */,
    },
  ],
  MetricName: "IncomingLogEvents",
  Namespace: "AWS/Logs",
};

cw.listMetrics(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Metrics", JSON.stringify(data.Metrics));
  }
});
```

Use `PutAnomalyDetector` with an AWS SDK or CLI

The following code examples show how to use `PutAnomalyDetector`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Add an anomaly detector for a single metric.
    /// </summary>
    /// <param name="anomalyDetector">A single metric anomaly detector.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> PutAnomalyDetector(SingleMetricAnomalyDetector
anomalyDetector)
```

```
    {
        var putAlarmDetectorResult = await
_amazonCloudWatch.PutAnomalyDetectorAsync(
            new PutAnomalyDetectorRequest()
            {
                SingleMetricAnomalyDetector = anomalyDetector
            });

        return putAlarmDetectorResult.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see PutAnomalyDetector in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To create an anomaly detection model

The following `put-anomaly-detector` example creates an anomaly detection model for a CloudWatch metric.

```
aws cloudwatch put-anomaly-detector \
    --namespace AWS/Logs \
    --metric-name IncomingBytes \
    --stat SampleCount
```

This command produces no output.

For more information, see Using CloudWatch anomaly detection in the *Amazon CloudWatch User Guide*.

- For API details, see PutAnomalyDetector in *AWS CLI Command Reference*.

 was created programmatically.
        var dashboardResponse = await _amazonCloudWatch.PutDashboardAsync(
            new PutDashboardRequest()
            {
                DashboardName = dashboardName,
                DashboardBody = dashboardBody
            });

        return dashboardResponse.DashboardValidationMessages;
    }
```

- For API details, see PutDashboard in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To create a dashboard

The following `put-dashboard` example creates a dashboard named `Dashboard-A` in the specified account.

```
aws cloudwatch put-dashboard \
    --dashboard-name Dashboard-A \
    --dashboard-body '{"widgets":
[{"height":6,"width":6,"y":0,"x":0,"type":"metric","properties":
{"view":"timeSeries","stacked":false,"metrics":
[["Namespace","CPUUtilization","Environment","Prod","Type","App"]],"region":"us-
east-1"}}]}'
```

Output:

```
{
    "DashboardValidationMessages": []
}
```

For more information, see Creating a CloudWatch dashboard in the *Amazon CloudWatch User Guide*.

- For API details, see PutDashboard in *AWS CLI Command Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `PutMetricAlarm` with an AWS SDK or CLI

The following code examples show how to use `PutMetricAlarm`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Get started with alarms
- Manage metrics and alarms

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/PutMetricAlarmRequest.h>
#include <iostream>
```

Create the alarm to watch the metric.

```
        Aws::CloudWatch::CloudWatchClient cw;
        Aws::CloudWatch::Model::PutMetricAlarmRequest request;
        request.SetAlarmName(alarm_name);
        request.SetComparisonOperator(
            Aws::CloudWatch::Model::ComparisonOperator::GreaterThanThreshold);
        request.SetEvaluationPeriods(1);
        request.SetMetricName("CPUUtilization");
        request.SetNamespace("AWS/EC2");
        request.SetPeriod(60);
        request.SetStatistic(Aws::CloudWatch::Model::Statistic::Average);
        request.SetThreshold(70.0);
        request.SetActionsEnabled(false);
        request.SetAlarmDescription("Alarm when server CPU exceeds 70%");
        request.SetUnit(Aws::CloudWatch::Model::StandardUnit::Seconds);

        Aws::CloudWatch::Model::Dimension dimension;
        dimension.SetName("InstanceId");
        dimension.SetValue(instanceId);

        request.AddDimensions(dimension);

        auto outcome = cw.PutMetricAlarm(request);
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to create CloudWatch alarm:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
        else
        {
            std::cout << "Successfully created CloudWatch alarm " << alarm_name
                << std::endl;
        }
```

- For API details, see PutMetricAlarm in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent

The following example uses the `put-metric-alarm` command to send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent:

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm
 when CPU exceeds 70 percent" --metric-name CPUUtilization --namespace AWS/
EC2 --statistic Average --period 300 --threshold 70 --comparison-
operator GreaterThanThreshold  --dimensions "Name=InstanceId,Value=i-12345678" --
evaluation-periods 2 --alarm-actions arn:aws:sns:us-east-1:111122223333:MyTopic
 --unit Percent
```

This command returns to the prompt if successful. If an alarm with the same name already exists, it will be overwritten by the new alarm.

To specify multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space:

```
aws cloudwatch put-metric-alarm --alarm-name "Default_Test_Alarm3" --alarm-
description "The default example alarm" --namespace "CW EXAMPLE METRICS"
 --metric-name Default_Test --statistic Average --period 60 --evaluation-
periods 3 --threshold 50 --comparison-operator GreaterThanOrEqualToThreshold --
dimensions Name=key1,Value=value1 Name=key2,Value=value2
```

- For API details, see PutMetricAlarm in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { PutMetricAlarmCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  // This alarm triggers when CPUUtilization exceeds 70% for one minute.
  const command = new PutMetricAlarmCommand({
    AlarmName: process.env.CLOUDWATCH_ALARM_NAME, // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
    ComparisonOperator: "GreaterThanThreshold",
    EvaluationPeriods: 1,
    MetricName: "CPUUtilization",
    Namespace: "AWS/EC2",
    Period: 60,
    Statistic: "Average",
    Threshold: 70.0,
    ActionsEnabled: false,
    AlarmDescription: "Alarm when server CPU exceeds 70%",
    Dimensions: [
      {
        Name: "InstanceId",
        Value: process.env.EC2_INSTANCE_ID, // Set the value of EC_INSTANCE_ID to
 the Id of an existing Amazon EC2 instance.
      },
    ],
    Unit: "Percent",
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
```

```
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

```
# Creates or updates an alarm in Amazon CloudWatch.
#
# @param cloudwatch_client [Aws::CloudWatch::Client]
#   An initialized CloudWatch client.
# @param alarm_name [String] The name of the alarm.
# @param alarm_description [String] A description about the alarm.
# @param metric_name [String] The name of the metric associated with the alarm.
```

```
# @param alarm_actions [Array] A list of Strings representing the
#   Amazon Resource Names (ARNs) to execute when the alarm transitions to the
#   ALARM state.
# @param namespace [String] The namespace for the metric to alarm on.
# @param statistic [String] The statistic for the metric.
# @param dimensions [Array] A list of dimensions for the metric, specified as
#   Aws::CloudWatch::Types::Dimension.
# @param period [Integer] The number of seconds before re-evaluating the metric.
# @param unit [String] The unit of measure for the statistic.
# @param evaluation_periods [Integer] The number of periods over which data is
#   compared to the specified threshold.
# @param theshold [Float] The value against which the specified statistic is
 compared.
# @param comparison_operator [String] The arithmetic operation to use when
#   comparing the specified statistic and threshold.
# @return [Boolean] true if the alarm was created or updated; otherwise, false.
# @example

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `PutMetricData` with an AWS SDK or CLI

The following code examples show how to use `PutMetricData`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Manage metrics and alarms

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/PutMetricDataRequest.h>
#include <iostream>
```

Put data into the metric.

```
        Aws::CloudWatch::CloudWatchClient cw;

        Aws::CloudWatch::Model::Dimension dimension;
        dimension.SetName("UNIQUE_PAGES");
        dimension.SetValue("URLS");

        Aws::CloudWatch::Model::MetricDatum datum;
        datum.SetMetricName("PAGES_VISITED");
        datum.SetUnit(Aws::CloudWatch::Model::StandardUnit::None);
        datum.SetValue(data_point);
        datum.AddDimensions(dimension);

        Aws::CloudWatch::Model::PutMetricDataRequest request;
        request.SetNamespace("SITE/TRAFFIC");
        request.AddMetricData(datum);

        auto outcome = cw.PutMetricData(request);
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to put sample metric data:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
        else
        {
            std::cout << "Successfully put sample metric data" << std::endl;
        }
```

- For API details, see PutMetricData in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To publish a custom metric to Amazon CloudWatch

The following example uses the `put-metric-data` command to publish a custom metric to Amazon CloudWatch:

```
aws cloudwatch put-metric-data --namespace "Usage Metrics" --metric-data file://
metric.json
```

The values for the metric itself are stored in the JSON file, `metric.json`.

Here are the contents of that file:

```
[
  {
    "MetricName": "New Posts",
    "Timestamp": "Wednesday, June 12, 2013 8:28:20 PM",
    "Value": 0.50,
    "Unit": "Count"
  }
]
```

For more information, see Publishing Custom Metrics in the *Amazon CloudWatch Developer Guide*.

To specify multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name=Value pair. Multiple dimensions are separated by a comma.:

```
aws cloudwatch put-metric-data --metric-name Buffers --
namespace MyNameSpace --unit Bytes --value 231434333 --
dimensions InstanceID=1-23456789,InstanceType=m1.small
```

- For API details, see PutMetricData in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { PutMetricDataCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  // See https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/
API_PutMetricData.html#API_PutMetricData_RequestParameters
  // and https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
publishingMetrics.html
  // for more information about the parameters in this command.
  const command = new PutMetricDataCommand({
    MetricData: [
      {
        MetricName: "PAGES_VISITED",
        Dimensions: [
          {
            Name: "UNIQUE_PAGES",
            Value: "URLS",
          },
        ],
        Unit: "None",
        Value: 1.0,
      },
    ],
    Namespace: "SITE/TRAFFIC",
```

```
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see PutMetricData in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

// Create parameters JSON for putMetricData
var params = {
  MetricData: [
```

```
    {
      MetricName: "PAGES_VISITED",
      Dimensions: [
        {
          Name: "UNIQUE_PAGES",
          Value: "URLS",
        },
      ],
      Unit: "None",
      Value: 1.0,
    },
  ],
  Namespace: "SITE/TRAFFIC",
};

cw.putMetricData(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", JSON.stringify(data));
  }
});
```

PowerShell

Tools for PowerShell V4

Example 1: Creates a new MetricDatum object, and writes it to Amazon Web Services CloudWatch Metrics.

```
### Create a MetricDatum .NET object
$Metric = New-Object -TypeName Amazon.CloudWatch.Model.MetricDatum
$Metric.Timestamp = [DateTime]::UtcNow
$Metric.MetricName = 'CPU'
$Metric.Value = 50

### Write the metric data to the CloudWatch service
Write-CWMetricData -Namespace instance1 -MetricData $Metric
```

- For API details, see PutMetricData in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Creates a new MetricDatum object, and writes it to Amazon Web Services CloudWatch Metrics.

```
### Create a MetricDatum .NET object
$Metric = New-Object -TypeName Amazon.CloudWatch.Model.MetricDatum
$Metric.Timestamp = [DateTime]::UtcNow
$Metric.MetricName = 'CPU'
$Metric.Value = 50

### Write the metric data to the CloudWatch service
Write-CWMetricData -Namespace instance1 -MetricData $Metric
```

- For API details, see PutMetricData in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Scenarios for CloudWatch using AWS SDKs

The following code examples show you how to implement common scenarios in CloudWatch with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within CloudWatch or combined with other AWS services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- Get started with CloudWatch alarms using an AWS SDK
- Manage CloudWatch metrics and alarms using an AWS SDK
- Monitor performance of Amazon DynamoDB using an AWS SDK

Get started with CloudWatch alarms using an AWS SDK

The following code example shows how to:

- Create an alarm.
- Disable alarm actions.
- Describe an alarm.
- Delete an alarm.

SAP ABAP

SDK for SAP ABAP

> **Note**

Monitor performance of Amazon DynamoDB using an AWS SDK

The following code example shows how to configure an application's use of DynamoDB to monitor performance.

Java

SDK for Java 2.x

This example shows how to configure a Java application to monitor the performance of DynamoDB. The application sends metric data to CloudWatch where you can monitor the performance.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch
- DynamoDB

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Security in Amazon CloudWatch

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to CloudWatch, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations

This documentation helps you understand how to apply the shared responsibility model when using Amazon CloudWatch. It shows you how to configure Amazon CloudWatch to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your CloudWatch resources.

Contents

- Data protection in Amazon CloudWatch
- Identity and access management for Amazon CloudWatch
- Compliance validation for Amazon CloudWatch
- Resilience in Amazon CloudWatch

- Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints
- Security considerations for Synthetics canaries

Data protection in Amazon CloudWatch

The AWS shared responsibility model applies to data protection in Amazon CloudWatch. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with CloudWatch or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Encryption in transit

CloudWatch uses end-to-end encryption of data in transit. For more information, see Encryption of data in transit.

Identity and access management for Amazon CloudWatch

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use CloudWatch resources. IAM is an AWS service that you can use with no additional charge.

- Amazon CloudWatch permissions reference

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in CloudWatch.

Service user – If you use the CloudWatch service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more CloudWatch features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in CloudWatch, see Troubleshooting Amazon CloudWatch identity and access.

Service administrator – If you're in charge of CloudWatch resources at your company, you probably have full access to CloudWatch. It's your job to determine which CloudWatch features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with CloudWatch, see How Amazon CloudWatch works with IAM.

IAM administrator – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to CloudWatch. To view example CloudWatch identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon CloudWatch.

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see AWS Signature Version 4 for API requests in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the *AWS IAM Identity Center User Guide* and AWS Multi-factor authentication in IAM in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the *IAM User Guide*.

An *IAM group* is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see Use cases for IAM users in the *IAM User Guide*.

IAM roles

An *IAM role* is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. To temporarily assume an IAM role in the AWS Management Console, you can switch from a user to an IAM role (console). You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Methods to assume a role in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Create a role for a third-party identity provider (federation) in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the *AWS IAM Identity Center User Guide*.
- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or

store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.
- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Use an IAM role to grant permissions to applications running on Amazon EC2 instances in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choose between managed policies and inline policies in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the *Amazon Simple Storage Service Developer Guide*.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see Service control policies in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – RCPs are JSON policies that you can use to set the maximum available permissions for resources in your accounts without updating the IAM policies attached to each resource that you own. The RCP limits permissions for resources in member accounts and can impact the effective permissions for identities, including the AWS account root user, regardless of whether they belong to your organization. For more information about Organizations and RCPs, including a list of AWS services that support RCPs, see Resource control policies (RCPs) in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's

permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon CloudWatch works with IAM

Before you use IAM to manage access to CloudWatch, learn what IAM features are available to use with CloudWatch.

The following tables list the IAM features that you can use with Amazon CloudWatch.

IAM feature	CloudWatch support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Principal permissions	Yes
Service roles	Yes

IAM feature	CloudWatch support
Service-linked roles	No

To get a high-level view of how CloudWatch and other AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

Identity-based policies for CloudWatch

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for CloudWatch

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Resource-based policies within CloudWatch

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for CloudWatch

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of CloudWatch actions, see Actions defined by Amazon CloudWatch in the *Service Authorization Reference*.

Policy actions in CloudWatch use the following prefix before the action:

```
cloudwatch
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "cloudwatch:action1",
      "cloudwatch:action2"
         ]
```

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Policy resources for CloudWatch

Supports policy resources: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of CloudWatch resource types and their ARNs, see Resources defined by Amazon CloudWatch in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions defined by Amazon CloudWatch.

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Policy condition keys for CloudWatch

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or `Condition` *block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use

condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, AWS evaluates them using a logical `AND` operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the *IAM User Guide*.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

To see a list of CloudWatch condition keys, see Condition keys for Amazon CloudWatch in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon CloudWatch.

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

ACLs in CloudWatch

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with CloudWatch

Supports ABAC (tags in policies): Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with CloudWatch

Supports temporary credentials: Yes

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the *IAM User Guide*.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switch from a user to an IAM role (console) in the *IAM User Guide*.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Cross-service principal permissions for CloudWatch

Supports forward access sessions (FAS): Yes

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a

different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

Service roles for CloudWatch

Supports service roles: Yes

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break CloudWatch functionality. Edit service roles only when CloudWatch provides guidance to do so.

Identity-based policy examples for Amazon CloudWatch

By default, users and roles don't have permission to create or modify CloudWatch resources. They also can't perform tasks by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or AWS API. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Create IAM policies (console) in the *IAM User Guide*.

For details about actions and resource types defined by CloudWatch, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Amazon CloudWatch in the *Service Authorization Reference*.

Topics

- Policy best practices
- Using the CloudWatch console

Policy best practices

Identity-based policies determine whether someone can create, access, or delete CloudWatch resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the CloudWatch console

To access the Amazon CloudWatch console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the CloudWatch resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that users and roles can still use the CloudWatch console, also attach the CloudWatch `ConsoleAccess` or `ReadOnly` AWS managed policy to the entities. For more information, see Adding permissions to a user in the *IAM User Guide*.

Permissions needed for CloudWatch console

The full set of permissions required to work with the CloudWatch console are listed below. These permissions provide full write and read access to the CloudWatch console.

- application-autoscaling:DescribeScalingPolicies
- autoscaling:DescribeAutoScalingGroups
- autoscaling:DescribePolicies
- cloudtrail:DescribeTrails
- cloudwatch:DeleteAlarms
- cloudwatch:DescribeAlarmHistory

Additionally, to view the X-Ray Trace Map, you need `AWSXrayReadOnlyAccess`

Troubleshooting Amazon CloudWatch identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with CloudWatch and IAM.

Topics

- I am not authorized to perform an action in CloudWatch
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my CloudWatch resources

I am not authorized to perform an action in CloudWatch

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional *`my-example-widget`* resource but doesn't have the fictional `cloudwatch:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 cloudwatch:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the *my-example-widget* resource by using the `cloudwatch:GetWidget` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to CloudWatch.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in CloudWatch. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my CloudWatch resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether CloudWatch supports these features, see How Amazon CloudWatch works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

CloudWatch dashboard permissions update

On May 1, 2018, AWS changed the permissions required to access CloudWatch dashboards. Dashboard access in the CloudWatch console now requires permissions that were introduced in 2017 to support dashboard API operations:

- **cloudwatch:GetDashboard**
- **cloudwatch:ListDashboards**
- **cloudwatch:PutDashboard**
- **cloudwatch:DeleteDashboards**

To access CloudWatch dashboards, you need one of the following:

- The **AdministratorAccess** policy.
- The **CloudWatchFullAccess** policy.
- A custom policy that includes one or more of these specific permissions:
  - `cloudwatch:GetDashboard` and `cloudwatch:ListDashboards` to be able to view dashboards
  - `cloudwatch:PutDashboard` to be able to create or modify dashboards
  - `cloudwatch:DeleteDashboards` to be able to delete dashboards

For more information about using policies to change permissions for an IAM user, see Changing Permissions for an IAM user.

For more information about CloudWatch permissions, see Amazon CloudWatch permissions reference.

For more information about dashboard API operations, see PutDashboard in the Amazon CloudWatch API Reference.

AWS managed (predefined) policies for CloudWatch

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases so that you can avoid having to investigate what permissions are needed. For more information, see AWS managed policies in the *IAM User Guide*.

The following AWS managed policies, which you can attach to users in your account, are specific to CloudWatch.

Topics

- CloudWatch updates to AWS managed policies
- CloudWatchFullAccessV2
- CloudWatchFullAccess
- CloudWatchReadOnlyAccess
- CloudWatchActionsEC2Access
- CloudWatch-CrossAccountAccess
- CloudWatchAutomaticDashboardsAccess
- CloudWatchAgentServerPolicy
- CloudWatchAgentAdminPolicy
- AWS managed (predefined) policies for CloudWatch cross-account observability
- AWS managed (predefined) policies for CloudWatch investigations
- AWS managed (predefined) policies for CloudWatch Application Signals
- AWS managed (predefined) policies for CloudWatch Synthetics
- AWS managed (predefined) policies for Amazon CloudWatch RUM
- AWS managed (predefined) policies for CloudWatch Evidently
- AWS managed policy for AWS Systems Manager Incident Manager

CloudWatch updates to AWS managed policies

View details about updates to AWS managed policies for CloudWatch since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the CloudWatch Document history page.

Change	Description	Date
CloudWatchApplicationSignalsReadOnlyAccess – Updated policy	CloudWatch updated the **CloudWatchApplicationSignalsReadOnlyAccess** policy to view how resources and services change in your account and view top observations for service anomalies in your account.	September 29, 2025
CloudWatchApplicationSignalsFullAccess – Updated policy	CloudWatch updated the **CloudWatchApplicationSignalsFullAccess** policy to view how resources and services change in your account and view top observations for service anomalies in your account.	September 29, 2025
AIOpsAssistantPolicy – Updated policy	CloudWatch updated the **AIOpsAssistantPolicy** to allow CloudWatch investigations access to additional resources to assist in queries, troubleshooting, and topology mapping. This policy grants CloudWatch investigations the necessary	September 24, 2025

Change	Description	Date
	permissions for conducting investigations.	
AIOpsConsoleAdminPolicy – Updated policy	CloudWatch updated the **AIOpsConsoleAdminPolicy** policy to permit validation of investigation groups across accounts. This policy grants users access to CloudWatch investigations actions, and to additiona l AWS actions that are necessary for accessing investigation events.	June 13, 2025
AIOpsOperatorAccess – Updated policy	CloudWatch updated the **AIOpsOperatorAccess** policy to permit validation of investigation groups across accounts. This policy grants users access to CloudWatch investigations actions, and to additiona l AWS actions that are necessary for accessing investigation events.	June 13, 2025

Change	Description	Date
AIOpsAssistantPolicy – Updates to existing policy	CloudWatch updated the **AIOpsAssistantPolicy** IAM policy. It added permissions to enable CloudWatch Application Insights operational investigations to find information in your resources during investigations. The following permissions were added: `appsync:GetGraphqlApi` , `appsync:GetDataSource` , `iam:ListAttachedRolePolicies` , `iam:ListRolePolicies` , and `iam:ListRoles` Additionally, the `elastic-inference:Describe*` permission was removed from the policy.	June 13, 2025

Change	Description	Date
AmazonCloudWatchRUMReadOnlyAccess – Updated policy	CloudWatch added permissions to the **AmazonCloudWatchRUMReadOnlyAccess** policy. The `synthetics:describeCanaries` and `synthetics:describeCanariesLastRun` was added so that CloudWatch RUM can display associated Synthetics Canaries to the RUM app monitor. The `cloudwatch:GetMetricData` was added so that CloudWatch RUM can display associated CloudWatch metrics to the RUM app monitor. The `cloudwatch:DescribeAlarms` was added so that CloudWatch RUM can display associated CloudWatch alarms to the RUM app monitor. The `logs:DescribeLogGroups` was added so that CloudWatch RUM can display associated CloudWatch logs to the RUM app monitor. The `xray:GetTraceSummaries` was added so that	June 28, 2025

Change	Description	Date
	CloudWatch RUM can display associated X-Ray Trace segments to the RUM app monitor. The `rum:ListTagsForResources` was added so that CloudWatch RUM can display associated tags to the RUM app monitor.	
AIOpsReadOnlyAccess – Updated policy	CloudWatch updated the **AIOpsReadOnlyAccess** policy to permit validation of investigation groups across accounts. This policy grants a user read-only permissions for Amazon AI Operations and other related services.	June 5, 2025
AmazonCloudWatchRUMReadOnlyAccess – Updated policy	CloudWatch added a permission to the **AmazonCloudWatchRUMReadOnlyAccess** policy. The `rum:GetResourcePolicy` permission was added so that CloudWatch RUM can view the resource policy attached to the RUM application monitor.	April 28, 2025

Change	Description	Date
AIOpsConsoleAdminPolicy – New policy	CloudWatch created a new policy named **AIOpsConsoleAdminPolicy**. This policy grants users full administrative access for managing CloudWatch investigations, including the management of trusted identity propagation, and the management of IAM Identity Center and organizational access.	December 3, 2024
AIOpsOperatorAccess – New policy	CloudWatch created a new policy named **AIOpsOperatorAccess**. This policy grants users access to CloudWatch investigations actions, and to additional AWS actions that are necessary for accessing investigation events.	December 3, 2024
AIOpsReadOnlyAccess – New policy	CloudWatch created a new policy named **AIOpsReadOnlyAccess**. This policy grants a user read-only permissions for Amazon AI Operations and other related services.	December 3, 2024

Change	Description	Date
AIOpsAssistantPolicy – New policy	CloudWatch created a new policy named **AIOpsAssistantPolicy**. You don't assign this policy to a user. You assign this policy to the Amazon AI Operations assistant to enable CloudWatch investigations to analyze your AWS resources during the investigation of operational events.	December 3, 2024
CloudWatchFullAccessV2 – Updates to existing policies	CloudWatch updated both **CloudWatchFullAccessV2** and **CloudWatchFullAccess**. Permissions for Amazon OpenSearch Service were added to to enable CloudWatch Logs integration with OpenSearch Service for some features.	December 1, 2024

Change	Description	Date
CloudWatchNetworkFlowMonitorServiceRolePolicy – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorServiceRolePolicy**. The **CloudWatchNetworkFlowMonitorServiceRolePolicy** grants permissions for Network Flow Monitor to publish metrics to CloudWatch. It also allows the service to use AWS Organizations to get information for multi-account scenarios.	December 1, 2024
CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy**. The **CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy** grants permissions for Network Flow Monitor to generate topology snapshots of resources used in your account.	December 1, 2024

Change	Description	Date
CloudWatchNetworkFlowMonitorAgentPublishPolicy – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorAgentPublishPolicy**. The **CloudWatchNetworkFlowMonitorAgentPublishPolicy** grants permissions for resources, such as Amazon EC2 and Amazon EKS instances, to send telemetry reports (metrics) to a Network Flow Monitor endpoint.	December 1, 2024

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch updated the policy named **CloudWatchSyntheticsFullAccess**. The following CloudWatch Logs actions have been added to allow CloudWatch Synthetics to get and use canary log data in Lambda log groups. The `lambda:GetFunction` permission has also been added to allow Synthetics to get information about a specific function. • `logs:GetLogRecord` – Required to expand a log entry in CloudWatch Logs Insights. (Required to view logs in the Synthetics console.) • `logs:DescribeLogStreams` – Required to list all log streams on a log group. • `logs:StartQuery` – Required to start a Logs Insights query (required in the Synthetics console to view logs). • `logs:GetLogEvents` –	November 20, 2024

Change	Description	Date
	Required to list log events from the specified log stream. Used for querying a specific log stream on a log group. • `logs:FilterLogEvents` – Required to view logs in a canary's log group. • `logs:GetLogGroupFields` – Required for running a Logs Insights query in the console. (The Synthetics console links to the Logs Insights query. Without this permission, Logs Insights queries on a log group fail.) Additionally, Lambda layer version actions now apply to all CloudWatch Synthetics layer ARNs.	

Change	Description	Date
CloudWatchInternetMonitorReadOnlyAccess – New **CloudWatchInternetMonitorReadOnlyAccess**. This policy grants read only access to resources and actions available in the CloudWatch console for Internet Monitor. The scope of this policy includes `internetmonitor:` so that users can use read-only Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch metrics. It includes some `logs:` policies to manage log queries.	November 14, 2024	

Change	Description	Date
CloudWatchInternetMonitorFullAccess – New policy	CloudWatch created a new policy named **CloudWatchInternetMonitorFullAccess**. This policy grants full access to resources and actions available in the CloudWatch console for Internet Monitor. The scope of this policy includes `internetmonitor:` so that users can use Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `logs:` policies to manage log queries. It includes some `ec2:`, `cloudfront:`, `elasticloadbalancing:`, and `workspaces:` policies to work with resources that you add to monitors so that Internet Monitor can create a traffic profile for your application. It contains some `iam:` policies to manage IAM roles.	October 23, 2024

Change	Description	Date
CloudWatchLambdaApplicationSignalsExecutionRolePolicy – New **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024	
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch updated the policy named **CloudWatchSyntheticsFullAccess**. The `lambda:ListTags` , `lambda:TagResource` , and `lambda:UntagResource` permissions were added so that when you apply or change tags on a canary, you can choose to have Synthetics also apply those same tags or changes to the Lambda function that the canary uses.	October 11, 2024

Change	Description	Date
CloudWatchApplicationSignalsReadOnlyAccess – New policy	CloudWatch created a new policy named **CloudWatchApplicationSignalsReadOnlyAccess**. This policy grants read only access to resources and actions available in the CloudWatch console for Application Signals. The scope of this policy includes `application-signals:` policies so that users can use read only actions and resources available in the CloudWatch console under Application Signals. It contains an `iam:` policy to manage IAM roles. It includes some `logs:` policies to manage log queries and filters. It includes `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `synthetics:` policies to retrive information about synthetics canaries. It includes `rum:` policies to manage RUM clients and jobs. It contains an `xray:` policy to obtain trace summaries.	June 7, 2024

Change	Description	Date
CloudWatchApplicationSignalsFullAccess – New policy	CloudWatch created a new policy named **CloudWatchApplicationSignalsFullAccess**. This policy grants full access to resources and actions available in the CloudWatch console for Application Signals. The scope of this policy includes `application-signals:` so that users can use Application Signals actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `logs:` policies to manage log queries. It includes some `synthetics:` policies to write and retrieve information about synthetics canaries. It includes `rum:` policies to manage RUM clients and jobs. It contains an `xray:` policy to obtain trace summaries. It includes some `cloudwatch:` policies to manage CloudWatch alarms. It contains some `iam:` policies to manage IAM roles. It includes some `sns:` policies to manage Amazon	June 7, 2024

Change	Description	Date
	Simple Notification Service notifications.	
CloudWatchFullAccessV2 – Update to an existing policy	CloudWatch updated the policy named **CloudWatchFullAccessV2**. The scope of the `CloudWatchFullAccessPermissions` policy was updated to add `application-signals:*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services.	May 20, 2024

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch updated the policy named **CloudWatchReadOnlyAccess**. The scope of the `CloudWatchReadOnlyAccessPermissions` policy was updated to add `application-signals:BatchGet*`, `application-signals:List*`, and `application-signals:Get*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services. The scope of `CloudWatchReadOnlyGetRolePermissions` was updated to add the `iam:GetRole` action so that users can check if CloudWatch Application Signals is set up.	May 20, 2024

Change	Description	Date
CloudWatchApplicationSignalsServiceRolePolicy – Update to an existing policy	CloudWatch updated the policy named **CloudWatchApplicationSignalsServiceRolePolicy**. The scoping of the `logs:StartQuery` and `logs:GetQueryResults` permissions was changed to add the `arn:aws:logs:*:*:log-group:/aws/appsignals/*:*` and `arn:aws:logs:*:*:log-group:/aws/application-signals/data:*` ARNs to enable Application Signals on more architectures.	April 18, 2024
CloudWatchApplicationSignalsServiceRolePolicy – Update to an existing policy	CloudWatch changed the scope of a permission in **CloudWatchApplicationSignalsServiceRolePolicy**. The scope of the `cloudwatch:GetMetricData` permission was changed to * so that Application Signals can retrieve metrics from sources in linked accounts.	April 08, 2024

Change	Description	Date
CloudWatchAgentServerPolicy – Update to an existing policy	CloudWatch added permissions to **CloudWatchAgentServerPolicy**. The `xray:PutTraceSegments`, `xray:PutTelemetryRecords`, `xray:GetSamplingRules`, `xray:GetSamplingTargets`, `xray:GetSamplingStatisticSummaries` and `logs:PutRetentionPolicy` permissions were added so that the CloudWatch agent can publish X-Ray traces and modify log group retention periods.	February 12, 2024

Change	Description	Date
CloudWatchAgentAdminPolicy – Update to an existing policy	CloudWatch added permissions to **CloudWatchAgentAdminPolicy**. The `xray:PutTraceSegments`, `xray:PutTelemetryRecords`, `xray:GetSamplingRules`, `xray:GetSamplingTargets`, `xray:GetSamplingStatisticSummaries` and `logs:PutRetentionPolicy` permissions were added so that the CloudWatch agent can publish X-Ray traces and modify log group retention periods.	February 12, 2024

Change	Description	Date
CloudWatchFullAccessV2 – Update to an existing policy	CloudWatch added permissions to **CloudWatchFullAccessV2**. Existing permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM actions and new permissions for CloudWatch Application Signals were added so that users with this policy can manage CloudWatch Application Signals. The permission to create the CloudWatch Application Signals service-linked role was added to allow CloudWatch Application Signals to discover telemetry data in logs, metrics, traces, and tags.	December 5, 2023

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. Existing read-only permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM actions and new read-only permissions for CloudWatch Application Signals were added so that users with this policy can triage and diagnose their service health issues as reported by CloudWatch Application Signals. The `cloudwatch:GenerateQuery` permission was added so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 5, 2023
CloudWatchReadOnlyAccess – Update to an existing policy.	CloudWatch added a permission to **CloudWatchReadOnlyAccess**. The `cloudwatch:GenerateQuery` permission was added, so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 01, 2023

Change	Description	Date
CloudWatchApplicationSignalsServiceRolePolicy – New policy	CloudWatch added a new policy **CloudWatchApplicationSignalsServiceRolePolicy**. The **CloudWatchApplicationSignalsServiceRolePolicy** grants an upcoming feature permissions to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data.	November 9, 2023
AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy – New policy	CloudWatch added a new policy **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy**. The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy** grants permission to CloudWatch to fetch Performance Insights metrics from databases on your behalf.	September 20, 2023

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added a permission to **CloudWatchReadOnlyAccess**. The `application-autoscaling:DescribeScalingPolicies` permission was added so that users with this policy can access information about Application Auto Scaling policies.	September 14, 2023
CloudWatchFullAccessV2 – New policy	CloudWatch added a new policy **CloudWatchFullAccessV2**. The **CloudWatchFullAccessV2** grants full access to CloudWatch actions and resources while better scoping the permissions granted to other services such as Amazon SNS and Amazon EC2 Auto Scaling. For more information, see CloudWatchFullAccessV2.	August 1, 2023

Change	Description	Date
AWSServiceRoleForInternetMonitor – Update to an existing policy	Amazon CloudWatch Internet Monitor added new permissions to monitor Network Load Balancer resources. The `elasticloadbalancing:DescribeLoadBalancers` and `ec2:DescribeNetworkInterfaces` permissions are required so that Internet Monitor can monitor customers' Network Load Balancer traffic by analyzing flow logs for NLB resources. For more information, see Using Internet Monitor.	July 15, 2023
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `logs:StartLiveTail` and `logs:StopLiveTail` permissions were added so that users with this policy can use the console to start and stop CloudWatch Logs live tail sessions. For more information, see Use live tail to view logs in near real time.	June 6, 2023

Change	Description	Date
CloudWatchCrossAccountSharingConfiguration – New policy	CloudWatch added a new policy to enable you to manage CloudWatch cross-account observability links that share CloudWatch metrics. For more information, see CloudWatch cross-account observability.	November 27, 2022
OAMFullAccess – New policy	CloudWatch added a new policy to enable you to fully manage CloudWatch cross-account observability links and sinks. For more information, see CloudWatch cross-account observability.	November 27, 2022
OAMReadOnlyAccess – New policy	CloudWatch added a new policy to enable you to view information about CloudWatch cross-account observability links and sinks. For more information, see CloudWatch cross-account observability.	November 27, 2022

Change	Description	Date
CloudWatchFullAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchFullAccess**. The `oam:ListSinks` and `oam:ListAttachedLinks` permissions were added so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability.	November 27, 2022
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `oam:ListSinks` and `oam:ListAttachedLinks` permissions were added so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability.	November 27, 2022

Change	Description	Date
AmazonCloudWatchRUMServiceRolePolicy – Update to an existing policy	CloudWatch RUM updated a condition key in **AmazonCloudWatchRUMServiceRolePolicy**. The `"Condition": { "StringEquals": { "cloudwatch:namespace": "AWS/RUM" } }` condition key was changed to the following so that CloudWatch RUM can send custom metrics to custom metric namespaces. `"Condition": { "StringLike": { "cloudwatch:namespace": [ "RUM/CustomMetrics/*", "AWS/RUM" ] } }`	February 2, 2023

Change	Description	Date
AmazonCloudWatchRUMReadOnlyAccess – Updated policy	CloudWatch added permissions the **AmazonCloudWatchRUMReadOnlyAccess** policy. The `rum:ListRumMetricsDestinations` and `rum:BatchGetRumMetricsDefinitions` permissions were added so that CloudWatch RUM can send extended metrics to CloudWatch and Evidently.	October 27, 2022
AmazonCloudWatchRUMServiceRolePolicy – Update to an existing policy	CloudWatch RUM added permissions to **AmazonCloudWatchRUMServiceRolePolicy**. The `cloudwatch:PutMetricData` permission was added so that CloudWatch RUM can send extended metrics to CloudWatch.	October 26, 2022

Change	Description	Date
CloudWatchEvidentlyReadOnlyAccess – Update to an existing policy	CloudWatch Evidently added permissions to **CloudWatchEvidentlyReadOnlyAccess**. The `evidently:GetSegment` , `evidently:ListSegments` , and `evidently:ListSegmentReferences` permissions were added so that users with this policy can see Evidently audience segments that have been created.	August 12, 2022
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added permissions to **CloudWatchSyntheticsFullAccess**. The `lambda:DeleteFunction` and `lambda:DeleteLayerVersion` permissions were added so that CloudWatch Synthetics can delete related resources when a canary is deleted. The `iam:ListAttachedRolePolicies` was added so that customers can view the policies that are attached to a canary's IAM role.	May 6, 2022

Change	Description	Date
AmazonCloudWatchRUMFullAccess – New policy	CloudWatch added a new policy to enable full management of CloudWatch RUM. CloudWatch RUM allows you to perform real user monitoring of your web application. For more information, see CloudWatch RUM.	November 29, 2021
AmazonCloudWatchRUMReadOnlyAccess – New policy	CloudWatch added a new policy to enable read-only access to CloudWatch RUM. CloudWatch RUM allows you to perform real user monitoring of your web application. For more information, see CloudWatch RUM.	November 29, 2021
CloudWatchEvidentlyFullAccess – New policy	CloudWatch added a new policy to enable full management of CloudWatch Evidently. CloudWatch Evidently allows you to perform A/B experiments of your web applications, and to roll them out gradually. For more information, see Perform launches and A/B experiments with CloudWatch Evidently.	November 29, 2021

Change	Description	Date
CloudWatchEvidentlyReadOnlyAccess – New policy	CloudWatch added a new policy to enable read-only access to CloudWatch Evidently. CloudWatch Evidently allows you to perform A/B experiments of your web applications, and to roll them out gradually. For more information, see Perform launches and A/B experiments with CloudWatch Evidently.	November 29, 2021
AWSServiceRoleForCloudWatchRUM – New managed policy	CloudWatch added a policy for a new service-linked role to allow CloudWatch RUM to pubish monitoring data to other relevant AWS services.	November 29, 2021

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added permissions to **CloudWatchSyntheticsFullAccess**, and also changed the scope of one permission. The `kms:ListAliases` permission was added so that users can list available AWS KMS keys that can be used to encrypt canary artifacts. The `kms:DescribeKey` permission was added so that users can see the details of keys that will be used to encrypt for canary artifacts. And the `kms:Decrypt` permission was added to enable users to decrypt canary artifacts. This decryption ability is limited to use on resources within Amazon S3 buckets. The `Resource` scope of the `s3:GetBucketLocation` permission was changed from `*` to `arn:aws:s3:::*` .	September 29, 2021

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added a permission to **CloudWatchSyntheticsFullAccess**. The `lambda:UpdateFunctionCode` permission was added so that users with this policy can change the runtime version of canaries.	July 20, 2021
AWSCloudWatchAlarms_ActionSSMIncidentsServiceRolePolicy – New managed policy	CloudWatch added a new managed IAM policy to allow CloudWatch to create incidents in AWS Systems Manager Incident Manager.	May 10, 2021
CloudWatchAutomaticDashboardsAccess – Update to an existing policy	CloudWatch added a permission to the **CloudWatchAutomaticDashboardsAccess** managed policy. The `synthetics:DescribeCanariesLastRun` permission was added to this policy to enable cross-account dashboard users to see details about CloudWatch Synthetics canary runs.	April 20, 2021
CloudWatch started tracking changes	CloudWatch started tracking changes for its AWS managed policies.	April 14, 2021

CloudWatchFullAccessV2

AWS recently added the **CloudWatchFullAccessV2** managed IAM policy. This policy grants full access to CloudWatch actions and resources and also more properly scopes the permissions granted for other services such as Amazon SNS and Amazon EC2 Auto Scaling. We recommend that you begin using this policy instead of using **CloudWatchFullAccess**. AWS plans to deprecate **CloudWatchFullAccess** in the near future.

It includes `application-signals:` permissions so that users can access all the functionality from the CloudWatch console under Application Signals. It includes some `autoscaling:Describe` permissions so that users with this policy can see the Auto Scaling actions that are associated with CloudWatch alarms. It includes some `sns` permissions so that users with this policy can retrieve create Amazon SNS topics and associate them with CloudWatch alarms. It includes IAM permissions so that users with this policy can view information about service-linked roles associated with CloudWatch. It includes the `oam:ListSinks` and `oam:ListAttachedLinks` permissions so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability.

It includes Amazon OpenSearch Service permissions to support vended logs dashboards in CloudWatch Logs, which are created with Amazon OpenSearch Service analytics.

It includes `rum`, `synthetics`, and `xray` permissions so that users can have full access to CloudWatch Synthetics, AWS X-Ray, and CloudWatch RUM, all of which are under the CloudWatch service.

To see the full contents of the policy, see CloudWatchFullAccessV2 in the *AWS Managed Policy Reference Guide*.

CloudWatchFullAccess

The **CloudWatchFullAccess** policy is on the path to deprecation. We recommend that you stop using it, and use CloudWatchFullAccessV2 instead.

CloudWatchReadOnlyAccess

The **CloudWatchReadOnlyAccess** policy grants read-only access to CloudWatch and related observability features.

The policy includes some `logs:` permissions, so that users with this policy can use the console to view CloudWatch Logs information and CloudWatch Logs Insights queries. It includes

`autoscaling:Describe*`, so that users with this policy can see the Auto Scaling actions that are associated with CloudWatch alarms. It includes the `application-signals:` permissions so that users can use Application Signals to monitor the health of their services. It includes `application-autoscaling:DescribeScalingPolicies`, so that users with this policy can access information about Application Auto Scaling policies. It includes `sns:Get*` and `sns:List*`, so that users with this policy can retrieve information about the Amazon SNS topics that receive notifications about CloudWatch alarms. It includes the `oam:ListSinks` and `oam:ListAttachedLinks` permissions, so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability. It includes the `iam:GetRole` permissions so that users can check if CloudWatch Application Signals have been set up.

It includes `rum`, `synthetics`, and `xray` permissions so that users can have read-only access to CloudWatch Synthetics, AWS X-Ray, and CloudWatch RUM, all of which are under the CloudWatch service.

To see the full contents of the policy, see CloudWatchReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchActionsEC2Access

The **CloudWatchActionsEC2Access** policy grants read-only access to CloudWatch alarms and metrics in addition to Amazon EC2 metadata. It also grants access to the Stop, Terminate, and Reboot API actions for EC2 instances.

To see the full contents of the policy, see CloudWatchActionsEC2Access in the *AWS Managed Policy Reference Guide*.

CloudWatch-CrossAccountAccess

The **CloudWatch-CrossAccountAccess** managed policy is used by the **CloudWatch-CrossAccountSharingRole** IAM role. This role and policy enable users of cross-account dashboards to view automatic dashboards in each account that is sharing dashboards.

To see the full contents of the policy, see CloudWatch-CrossAccountAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchAutomaticDashboardsAccess

The **CloudWatchAutomaticDashboardsAccess** managed policy grants access to CloudWatch for non-CloudWatch APIs, so that resources such as Lambda functions can be displayed on CloudWatch automatic dashboards.

To see the full contents of the policy, see CloudWatchAutomaticDashboardsAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchAgentServerPolicy

The **CloudWatchAgentServerPolicy** policy can be used in IAM roles that are attached to Amazon EC2 instances to allow the CloudWatch agent to read information from the instance and write it to CloudWatch.

To see the full contents of the policy, see CloudWatchAgentServerPolicy in the *AWS Managed Policy Reference Guide*.

CloudWatchAgentAdminPolicy

The **CloudWatchAgentAdminPolicy** policy can be used in IAM roles that are attached to Amazon EC2 instances. This policy allows the CloudWatch agent to read information from the instance and write it to CloudWatch, and also to write information to Parameter Store.

To see the full contents of the policy, see CloudWatchAgentAdminPolicy in the *AWS Managed Policy Reference Guide*.

> **Note**
>
> You can review these permissions policies by signing in to the IAM console and searching for specific policies there.

You can also create your own custom IAM policies to allow permissions for CloudWatch actions and resources. You can attach these custom policies to the IAM users or groups that require those permissions.

AWS managed (predefined) policies for CloudWatch cross-account observability

The policies in this section grant permissions related to CloudWatch cross-account observability. For more information, see CloudWatch cross-account observability.

CloudWatchCrossAccountSharingConfiguration

The **CloudWatchCrossAccountSharingConfiguration** policy grants access to create, manage, and view Observability Access Manager links for sharing CloudWatch resources between accounts. For more information, see CloudWatch cross-account observability.

To see the full contents of the policy, see CloudWatchCrossAccountSharingConfiguration in the *AWS Managed Policy Reference Guide*.

OAMFullAccess

The **OAMFullAccess** policy grants access to create, manage, and view Observability Access Manager sinks and links, which are used for CloudWatch cross-account observability.

The **OAMFullAccess** policy by itself does not permit you to share observability data across links. To create a link to share CloudWatch metrics, you also need either **CloudWatchFullAccess** or **CloudWatchCrossAccountSharingConfiguration**. To create a link to share CloudWatch Logs log groups, you also need either **CloudWatchLogsFullAccess** or **CloudWatchLogsCrossAccountSharingConfiguration**. To create a link to share X-Ray traces, you also need either **AWSXRayFullAccess** or **AWSXRayCrossAccountSharingConfiguration**.

For more information, see CloudWatch cross-account observability.

To see the full contents of the policy, see OAMFullAccess in the *AWS Managed Policy Reference Guide*.

OAMReadOnlyAccess

The **OAMReadOnlyAccess** policy grants read-only access to Observability Access Manager resources, which are used for CloudWatch cross-account observability. For more information, see CloudWatch cross-account observability.

To see the full contents of the policy, see OAMReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for CloudWatch investigations

The policies in this section grant permissions related to CloudWatch investigations. For more information, see CloudWatch investigations.

AIOpsConsoleAdminPolicy

The **AIOpsConsoleAdminPolicy** policy grants full access to all CloudWatch investigations actions and their required permissions via the AWS console. This policy also grants limited access to other service's APIs required for CloudWatch investigations functionality.

- The `aiops` permissions grant access to all CloudWatch investigations actions.

- The `organizations`, `sso`, `identitystore`, and `sts` permissions allow actions needed for IAM Identity Center management which facilitate identity-aware sessions.
- The `ssm` permissions are required for SSM Ops Item integration with third-party issue management.
- The `iam` permissions are needed so that administrators can pass IAM roles to the `aiops` and `ssm.integrations` services, and the role is later used by the assistant to analyze AWS resources

> **Important**
>
> These permissions allow users with this policy to pass any IAM role to the `aiops` and `ssm.integrations` services.

- It allows APIs from services outside CloudWatch investigations, which are required for investigation feature functionality. These include actions to configure Amazon Q Developer in chat applications, AWS KMS, CloudTrail trails, and SSM third-party issue management.

To see the full contents of the policy, see AIOpsConsoleAdminPolicy in the *AWS Managed Policy Reference Guide*.

AIOpsOperatorAccess

The **AIOpsOperatorAccess** policy grants access to a limited set of CloudWatch investigations APIs which include creating, updating, and deleting investigations, investigation events, and investigation resources.

This policy only provides access to investigations. You should be sure that IAM principals with this policy also have permissions to read CloudWatch observability data such as metrics, SLOs, and CloudWatch Logs query results.

- The `aiops` permissions allow access to CloudWatch investigations APIs to create, update, and delete investigations.
- The `sso`, `identitystore`, and `sts` permissions allow actions needed for IAM Identity Center management which facilitate identity-aware sessions.
- The `ssm` permissions are required for SSM Ops Item integration with third-party issue management.

To see the full contents of the policy, see AIOpsOperatorAccess in the *AWS Managed Policy Reference Guide*.

AIOpsReadOnlyAccess

The **AIOpsReadOnlyAccess** policy grants read-only permissions for CloudWatch investigations and other related services.

- The `aiops` permissions allow access to CloudWatch investigations APIs to get, list, and validate investigation groups.
- The `sso` permissions allow actions needed for IAM Identity Center management which facilitate identity-aware sessions.
- The `ssm` permissions are required for SSM Ops Item integration with third-party issue management.

To see the full contents of the policy, see AIOpsReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

IAM policy for CloudWatch investigations (AIOpsAssistantPolicy)

The **AIOpsAssistantPolicy** policy is not to be assigned to users or administrators. Instead, it is assigned **AIOpsAssistantPolicy** to Amazon AI Operations to enable it to analyze your AWS resources during investigations of operational events. This policy is scoped based on the resources that CloudWatch investigations supports during investigations, and will be updated as more resources are supported.

You can also choose to assign the general AWS **ReadOnlyAccess** to the assistant in addition to assigning it **AIOpsAssistantPolicy**. The reason to do this is that **ReadOnlyAccess** will be updated more frequently by AWS with permissions for new AWS services and actions that are released. The **AIOpsAssistantPolicy** will also be updated for new actions, but not as frequently.

To see the full contents of the policy, see AIOpsAssistantPolicy in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for CloudWatch Application Signals

The policies in this section grant permissions related to CloudWatch Application Signals. For more information, see Application Signals.

CloudWatchApplicationSignalsReadOnlyAccess

AWS has added the **CloudWatchApplicationSignalsReadOnlyAccess** managed IAM policy. This policy grants read only access to actions and resources available to users in the CloudWatch console under Application Signals. It includes `application-signals:` policies so that users can use CloudWatch Application signals to view, investigate and monitor the health of their services. It includes an `iam:GetRole` policy to allow users to retrieve information about an IAM role. It includes `logs:` policies to start and stop queries, retrieve the configuration for a metruc filter, and obtain query results. It includes `cloudwatch:` policies so that users can obtain information about a CloudWatch alarm or metrics. It includes `synthetics:` policies so that users can retrieve information about synthetics canary runs. It includes `rum:` policies to run batch operations, retrieve data, and update metrics definitions for RUM clients. It includes an `xray:` policy to retrieve trace summaries.

To see the full contents of the policy, see CloudWatchApplicationSignalsReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchApplicationSignalsFullAccess

AWS has added the **CloudWatchApplicationSignalsFullAccess** managed IAM policy. This policy grants access to all actions and resources available to users in the CloudWatch console. It includes `application-signals:` policies so that users can use CloudWatch Application signals to view, investigate and monitor the health of their services. It uses `cloudwatch:` policies to retrieve data from metrics and alarms. It uses `logs:` policies to manage queries and filters. It uses `synthetics:` policies so that users can retrieve information about synthetics canary runs. It includes `rum:` policies to run batch operations, retrieve data and update metrics definitions for RUM clients. It includes an `xray:` policy to retrieve trace summaries. It includes `arn:aws:cloudwatch:*:*:alarm:` policies so that users can retrieve information about a service level objective (SLO) alarm. It includes `iam:` policies to manage IAM roles. It uses `sns:` policies to create, list, and subscribe to an Amazon SNS topic.

To see the full contents of the policy, see CloudWatchApplicationSignalsFullAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchLambdaApplicationSignalsExecutionRolePolicy

This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.

To see the full contents of the policy, see CloudWatchLambdaApplicationSignalsExecutionRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for CloudWatch Synthetics

The **CloudWatchSyntheticsFullAccess** and **CloudWatchSyntheticsReadOnlyAccess** AWS managed policies are available for you to assign to users who will manage or use CloudWatch Synthetics. The following additional policies are also relevant:

- **AmazonS3ReadOnlyAccess** and **CloudWatchReadOnlyAccess** – These are necessary to read all Synthetics data in the CloudWatch console.
- **AWSLambdaReadOnlyAccess** – Required to view the source code used by canaries.
- **CloudWatchSyntheticsFullAccess** – Allows you to create canaries. Additionally, to create and delete canaries that have a new IAM role created for them, you need specific inline policy permissions.

> **Important**
>
> Granting a user the `iam:CreateRole`, `iam:DeleteRole`, `iam:CreatePolicy`, `iam:DeletePolicy`, `iam:AttachRolePolicy`, and `iam:DetachRolePolicy` permissions gives that user full administrative access to create, attach, and delete roles and policies that have ARNs that match `arn:aws:iam::*:role/service-role/CloudWatchSyntheticsRole*` and `arn:aws:iam::*:policy/service-role/CloudWatchSyntheticsPolicy*`. For example, a user with these permissions can create a policy that has full permissions for all resources, and attach that policy to any role that matches that ARN pattern. Be careful to whom you grant these permissions.

For information about attaching policies and granting permissions to users, see Changing Permissions for an IAM User and To embed an inline policy for a user or role.

CloudWatchSyntheticsFullAccess

To see the full contents of the policy, see CloudWatchSyntheticsFullAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchSyntheticsReadOnlyAccess

To see the full contents of the policy, see CloudWatchSyntheticsReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for Amazon CloudWatch RUM

The **AmazonCloudWatchRUMFullAccess** and **AmazonCloudWatchRUMReadOnlyAccess** AWS managed policies are available for you to assign to users who will manage or use CloudWatch RUM.

AmazonCloudWatchRUMFullAccess

To see the full contents of the policy, see AmazonCloudWatchRUMFullAccess in the *AWS Managed Policy Reference Guide*.

AmazonCloudWatchRUMReadOnlyAccess

The **AmazonCloudWatchRUMReadOnlyAccess** allows read-only administrative access to CloudWatch RUM.

- The `synthetics` permission allows displaying associated Synthetics Canaries to the RUM app monitor
- The `cloudwatch` permission allows displaying associated CloudWatch metrics to the RUM app monitor
- The `cloudwatch alarms` permission allows displaying associated CloudWatch alarms to the RUM app monitor
- The `cloudwatch logs` permission allows displaying associated CloudWatch logs to the RUM app monitor
- The `x-ray` permission allows displaying associated X-Ray Trace segments to the RUM app monitor
- The `rum` permission allows displaying associated tags to the RUM app monitor

To see the full contents of the policy, see AmazonCloudWatchRUMReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AmazonCloudWatchRUMServiceRolePolicy

You can't attach **AmazonCloudWatchRUMServiceRolePolicy** to your IAM entities. This policy is attached to a service-linked role that allows CloudWatch RUM to publish monitoring data to other

relevant AWS services. For more information about this service linked role, see Using service-linked roles for CloudWatch RUM.

To see the full contents of the policy, see AmazonCloudWatchRUMServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for CloudWatch Evidently

The **CloudWatchEvidentlyFullAccess** and **CloudWatchEvidentlyReadOnlyAccess** AWS managed policies are available for you to assign to users who will manage or use CloudWatch Evidently.

CloudWatchEvidentlyFullAccess

To see the full contents of the policy, see CloudWatchEvidentlyFullAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchEvidentlyReadOnlyAccess

To see the full contents of the policy, see CloudWatchEvidentlyReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy for AWS Systems Manager Incident Manager

The **AWSCloudWatchAlarms_ActionSSMIncidentsServiceRolePolicy** policy is attached to a service-linked role that allows CloudWatch to start incidents in AWS Systems Manager Incident Manager on your behalf. For more information, see Service-linked role permissions for CloudWatch alarms Systems Manager Incident Manager actions.

The policy has the following permission:

- ssm-incidents:StartIncident

Customer managed policy examples

In this section, you can find example user policies that grant permissions for various CloudWatch actions. These policies work when you are using the CloudWatch API, AWS SDKs, or the AWS CLI.

Examples

- Example 1: Allow user full access to CloudWatch

- Example 2: Allow read-only access to CloudWatch
- Example 3: Stop or terminate an Amazon EC2 instance

Example 1: Allow user full access to CloudWatch

To grant a user full access to CloudWatch, you can use grant them the **CloudWatchFullAccess** managed policy instead of creating a customer-managed policy. The contents of the **CloudWatchFullAccess** are listed in CloudWatchFullAccess.

Example 2: Allow read-only access to CloudWatch

The following policy allows a user read-only access to CloudWatch and view Amazon EC2 Auto Scaling actions, CloudWatch metrics, CloudWatch Logs data, and alarm-related Amazon SNS data.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Action": [
        "autoscaling:Describe*",
        "cloudwatch:Describe*",
        "cloudwatch:Get*",
        "cloudwatch:List*",
        "logs:Get*",
        "logs:Describe*",
        "logs:StartQuery",
        "logs:StopQuery",
        "logs:TestMetricFilter",
        "logs:FilterLogEvents",
        "logs:StartLiveTail",
        "logs:StopLiveTail",
        "sns:Get*",
        "sns:List*"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
```

```
}
```

Example 3: Stop or terminate an Amazon EC2 instance

The following policy allows an CloudWatch alarm action to stop or terminate an EC2 instance. In the sample below, the GetMetricData, ListMetrics, and DescribeAlarms actions are optional. It is recommended that you include these actions to ensure that you have correctly stopped or terminated the instance.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Action": [
        "cloudwatch:PutMetricAlarm",
        "cloudwatch:GetMetricData",
        "cloudwatch:ListMetrics",
        "cloudwatch:DescribeAlarms"
      ],
      "Resource": [
        "*"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "ec2:DescribeInstanceStatus",
        "ec2:DescribeInstances",
        "ec2:StopInstances",
        "ec2:TerminateInstances"
      ],
      "Resource": [
        "*"
      ],
      "Effect": "Allow"
    }
  ]
}
```

Using condition keys to limit access to CloudWatch

See the following topics to learn about the service-specific condition keys that can be used in the `Condition` element of an IAM policy. You can use these keys to further refine the conditions under which the policy statement applies.

- Using condition keys to limit access to CloudWatch namespaces
- Using condition keys to limit Contributor Insights users' access to log groups
- Using condition keys to limit alarm actions
- Condition keys for CloudWatch Observability Admin

To see the global condition keys that are available to all services, see Available global condition keys.

Using condition keys to limit access to CloudWatch namespaces

Use IAM condition keys to limit users to publishing metrics only in the CloudWatch namespaces that you specify. This section provides examples that describe how to allow and exclude users from publishing metrics in a namespace.

Allowing publishing in one namespace only

The following policy limits the user to publishing metrics only in the namespace named `MyCustomNamespace`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Resource": "*",
        "Action": "cloudwatch:PutMetricData",
        "Condition": {
            "StringEquals": {
                "cloudwatch:namespace": "MyCustomNamespace"
            }
        }
    }
```

```
}
```

Excluding publishing from a namespace

The following policy allows the user to publish metrics in any namespace except for `CustomNamespace2`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData"
        },
        {
            "Effect": "Deny",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData",
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": "CustomNamespace2"
                }
            }
        }
    ]
}
```

Using condition keys to limit Contributor Insights users' access to log groups

To create a rule in Contributor Insights and see its results, a user must have the `cloudwatch:PutInsightRule` permission. By default, a user with this permission can create a Contributor Insights rule that evaluates any log group in CloudWatch Logs and then see the results. The results can contain contributor data for those log groups.

You can create IAM policies with condition keys to grant users the permission to write Contributor Insights rules for some log groups while preventing them from writing rules for and seeing this data from other log groups.

For more information about the `Condition` element in IAM policies, see IAM JSON policy elements: Condition.

Allow access to write rules and view results for only certain log groups

The following policy allows the user access to write rules and view results for the log group named `AllowedLogGroup` and all log groups that have names that start with `AllowedWildCard`. It does not grant access to write rules or view rule results for any other log groups.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCertainLogGroups",
            "Effect": "Allow",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*",
            "Condition": {
                "ForAllValues:StringEqualsIgnoreCase": {
                    "cloudwatch:requestInsightRuleLogGroups": [
                        "AllowedLogGroup",
                        "AllowedWildcard*"
                    ]
                }
            }
        }
    ]
}
```

Deny writing rules for specific log groups but allow writing rules for all other log groups

The following policy explicitly denies the user access to write rules and view rule results for the log group named `ExplicitlyDeniedLogGroup`, but allows writing rules and viewing rule results for all other log groups.

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowInsightRulesOnLogGroupsByDefault",
            "Effect": "Allow",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*"

        },
        {
            "Sid": "ExplicitDenySomeLogGroups",
            "Effect": "Deny",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*",
            "Condition": {
                "ForAllValues:StringEqualsIgnoreCase": {
                    "cloudwatch:requestInsightRuleLogGroups": [
                        "/test/alpine/ExplicitlyDeniedLogGroup"
                    ]
                }
            }
        }
    ]
}
```

Using condition keys to limit alarm actions

When CloudWatch alarms change state, they can perform different actions such as stopping and terminating EC2 instances and performing Systems Manager actions. These actions can be initiated when the alarm changes to any state, including ALARM, OK, or INSUFFICIENT_DATA.

Use the `cloudwatch:AlarmActions` condition key to allow a user to create alarms that can only perform the actions you specify when the alarm state changes. For example, you can allow a user to create alarms that can only perform actions which are not EC2 actions.

Allow a user to create alarms that can only send Amazon SNS notifications or perform Systems Manager actions

The following policy limits the user to creating alarms that can only send Amazon SNS notifications and perform Systems Manager actions. The user can't create alarms that perform EC2 actions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CreateAlarmsThatCanPerformOnlySNSandSSMActions",
            "Effect": "Allow",
            "Action": "cloudwatch:PutMetricAlarm",
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "cloudwatch:AlarmActions": [
                        "arn:aws:sns:*",
                        "arn:aws:ssm:*"
                    ]
                }
            }
        }
    ]
}
```

Condition keys for CloudWatch Observability Admin

You can use IAM policies to control access to Amazon CloudWatch Observability Admin resources and actions by using condition keys.

Observability Admin has the following condition keys:

Condition Key	Description	Type
CentralizationSourceRegions	ArrayOfString	Filters access by the source Regions that are passed in the request
CentralizationDestinationRegion	String	Filters access by the destination Region that is passed in the request

Condition Key	Description	Type
CentralizationBackupRegion	String	Filters access by the backup Region that is passed in the request

CentralizationSourceRegions

Filters access by the backup region specified for centralization rules.

- *Availability* – This key is available for the following resource types: organization-centralization-rule
- *Value type* – String

Example Example JSON policy with observabilityadmin:CentralizationBackupRegion

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "observabilityadmin:CreateOrganizationCentralizationRule",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "observabilityadmin:CentralizationBackupRegion": "us-west-2"
        }
      }
    }
  ]
}
```

CentralizationDestinationRegion

Filters access by the destination region specified for centralization rules.

- *Availability* – This key is available for the following resource types: organization-centralization-rule
- *Value type* – String

Example Example JSON policy with observabilityadmin:CentralizationDestinationRegion

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "observabilityadmin:CreateOrganizationCentralizationRule",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "observabilityadmin:CentralizationDestinationRegion": "us-east-1"
        }
      }
    }
  ]
}
```

CentralizationBackupRegion

Filters access by the source regions specified for centralization rules.

- *Availability* – This key is available for the following resource types: organization-centralization-rule
- *Value type* – List of strings

Example Example JSON policy with observabilityadmin:CentralizationSourceRegions

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "observabilityadmin:CreateOrganizationCentralizationRule",
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringEquals": {
          "observabilityadmin:CentralizationSourceRegions": ["us-west-1", "us-west-2"]
        }
      }
    }
  ]
```

```
}
```

Using service-linked roles for CloudWatch

Amazon CloudWatch uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch. Service-linked roles are predefined by CloudWatch and include all the permissions that the service requires to call other AWS services on your behalf.

One service-linked role in CloudWatch makes setting up CloudWatch alarms that can terminate, stop, or reboot an Amazon EC2 instance without requiring you to manually add the necessary permissions. Another service-linked role enables a monitoring account to access CloudWatch data from other accounts that you specify, to build cross-account cross-Region dashboards.

CloudWatch defines the permissions of these service-linked roles, and unless defined otherwise, only CloudWatch can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This restriction protects your CloudWatch resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch alarms EC2 actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchEvents** – CloudWatch uses this service-linked role to perform Amazon EC2 alarm actions.

The AWSServiceRoleForCloudWatchEvents service-linked role trusts the CloudWatch Events service to assume the role. CloudWatch Events invokes the terminate, stop, or reboot instance actions when called upon by the alarm.

The AWSServiceRoleForCloudWatchEvents service-linked role permissions policy allows CloudWatch Events to complete the following actions on Amazon EC2 instances:

- `ec2:StopInstances`
- `ec2:TerminateInstances`

- ec2:RecoverInstances
- ec2:DescribeInstanceRecoveryAttribute
- ec2:DescribeInstances
- ec2:DescribeInstanceStatus

The **AWSServiceRoleForCloudWatchCrossAccount** service-linked role permissions policy allows CloudWatch to complete the following actions:

- sts:AssumeRole

Service-linked role permissions for CloudWatch telemetry config

CloudWatch observability admin creates and uses a service-linked role named **AWSServiceRoleForObservabilityAdmin** – CloudWatch uses this service-linked role to support resource and telemetry config discovery for AWS Organizations. The role is created in all member accounts of the Organization.

The **AWSServiceRoleForObservabilityAdmin** service-linked role trusts Observability Admin to assume the role. Observability Admin manages AWS Config Service Linked Configuration Recorders and Service Linked Configuration Aggregator in your Organizations accounts.

The **AWSServiceRoleForObservabilityAdmin** service-linked role has a policy, called AWSObservabilityAdminServiceRolePolicy, attached and this policy grants permission to CloudWatch Observability Admin to complete the following actions:

- organizations:ListAccounts
- organizations:ListAccountsForParent
- organizations:ListChildren
- organizations:ListParents
- organizations:DescribeOrganization
- organizations:DescribeOrganizationalUnit
- organizations:EnableAWSServiceAccess
- organizations:ListDelegatedAdministrators
- config:PutServiceLinkedConfigurationRecorder
- config:DeleteServiceLinkedConfigurationRecorder

- config:PutConfigurationAggregator
- config:DeleteConfigurationAggregator
- config:SelectAggregateResourceConfig
- iam:CreateServiceLinkedRole
- iam:PassRole

The complete contents of the AWSObservabilityAdminServiceRolePolicy policy are as follows:

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "organizations:ListAccounts",
    "organizations:ListAccountsForParent",
    "organizations:ListChildren",
    "organizations:ListParents",
    "organizations:DescribeOrganization",
    "organizations:DescribeOrganizationalUnit"
   ],
   "Resource": "*"
  },
  {
   "Effect": "Allow",
   "Action": [
    "config:PutServiceLinkedConfigurationRecorder",
    "config:DeleteServiceLinkedConfigurationRecorder"
   ],
   "Resource": [
    "arn:aws:config:*:*:configuration-recorder/
AWSConfigurationRecorderForObservabilityAdmin/*"
   ]
  },
  {
   "Effect": "Allow",
   "Action": [
    "config:PutConfigurationAggregator",
```

```
    "config:DeleteConfigurationAggregator",
    "config:SelectAggregateResourceConfig"
   ],
   "Resource": [
    "arn:aws:config:*:*:config-aggregator/aws-service-config-aggregator/
observabilityadmin.amazonaws.com/*"
   ]
  },
  {
   "Effect": "Allow",
   "Action": [
    "iam:CreateServiceLinkedRole"
   ],
   "Resource": [
    "arn:aws:iam::*:role/aws-service-role/config.amazonaws.com/
AWSServiceRoleForConfig"
   ],
   "Condition": {
    "StringEquals": {

       "observabilityadmin.amazonaws.com",
       "config.amazonaws.com"
      ]
     }
    }
   }
  ]
}
```

Service-linked role permissions for CloudWatch telemetry enablement

The `AWSObservabilityAdminTelemetryEnablementServiceRolePolicy` grants permissions necessary to enable and manage telemetry configurations for AWS resources based on telemetry rules.

This policy grants permissions for:

- Basic telemetry operations including describing VPCs, flow logs, log groups, and managing EC2 instance monitoring

- Resource tagging operations with the `CloudWatchTelemetryRuleManaged` tag for tracking managed resources
- Log delivery configuration for services like AWS Bedrock and VPC Flow Logs
- Configuration recorder management for telemetry enablement tracking

The policy enforces security boundaries through conditions that:

- Restrict operations to resources within the same account using `aws:ResourceAccount`
- Require the `CloudWatchTelemetryRuleManaged` tag for resource modifications
- Limit configuration recorder access to those associated with telemetry enablement

The complete contents of the AWSObservabilityAdminTelemetryEnablementServiceRolePolicy are as follows:

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",

```

Service-linked role permissions for CloudWatch Application Signals

CloudWatch Application Signals uses the service-linked role named **AWSServiceRoleForCloudWatchApplicationSignals** – CloudWatch uses this service-linked role to

collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals.

The **AWSServiceRoleForCloudWatchApplicationSignals** service-linked role trusts CloudWatch Application Signals to assume the role. Application Signals collects the logs, traces, metrics, and tags data from your account.

The **AWSServiceRoleForCloudWatchApplicationSignals** has an IAM policy attached, and this policy is named **CloudWatchApplicationSignalsServiceRolePolicy**. This policy grants permission to CloudWatch Application Signals to collect monitoring and tagging data from other relevant AWS services. It includes permissions for Application Signals to complete the following actions:

- `xray` – Retrieve X-Ray traces.
- `logs` – Retrieve the current CloudWatch logs information.
- `cloudwatch` – Retrieve the current CloudWatch metric information.
- `tags` – Retrieve the current tags.
- `application-signals` – Retrieve information on SLOs and their associated time exclusion windows.
- `autoscaling` – Retrieve application tags from Amazon EC2 Autoscaling group.

The complete contents of **CloudWatchApplicationSignalsServiceRolePolicy** are as follows:

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Sid": "XRayPermission",
   "Effect": "Allow",
   "Action": [

```

Service-linked role permissions for CloudWatch alarms Systems Manager OpsCenter actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchAlarms_ActionSSM** – CloudWatch uses this service-linked role to perform Systems Manager OpsCenter actions when a CloudWatch alarm goes into ALARM state.

The AWSServiceRoleForCloudWatchAlarms_ActionSSM service-linked role trusts the CloudWatch service to assume the role. CloudWatch alarms invoke the Systems Manager OpsCenter actions when called upon by the alarm.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSM** service-linked role permissions policy allows Systems Manager to complete the following actions:

- `ssm:CreateOpsItem`

Service-linked role permissions for CloudWatch alarms Systems Manager Incident Manager actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** – CloudWatch uses this service-linked role to start Incident Manager incidents when a CloudWatch alarm goes into ALARM state.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** service-linked role trusts the CloudWatch service to assume the role. CloudWatch alarms invoke the Systems Manager Incident Manager action when called upon by the alarm.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** service-linked role permissions policy allows Systems Manager to complete the following actions:

- `ssm-incidents:StartIncident`

Service-linked role permissions for CloudWatch cross-account cross-Region

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchCrossAccount** – CloudWatch uses this role to access CloudWatch data in other AWS accounts that you specify. The SLR only provides the assume role permission to allow the CloudWatch service to assume the role in the sharing account. It is the sharing role that provides access to data.

The **AWSServiceRoleForCloudWatchCrossAccount** service-linked role permissions policy allows CloudWatch to complete the following actions:

- `sts:AssumeRole`

The **AWSServiceRoleForCloudWatchCrossAccount** service-linked role trusts the CloudWatch service to assume the role.

Service-linked role permissions for CloudWatch database Performance Insights

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** – CloudWatch uses this role to retrieve Performance Insights metrics for creating alarms and snapshotting.

The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role has the `AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy` IAM policy attached. The contents of that policy are as follows:

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "pi:GetResourceMetrics"
   ],
   "Resource": "*",
   "Condition": {
    "StringEquals": {
     "aws:ResourceAccount": "${aws:PrincipalAccount}"
    }
   }
```

```
  }
 ]
}
```

The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role trusts the CloudWatch service to assume the role.

Service-linked role permissions for CloudWatch Logs centralization

CloudWatch uses the service-linked role named **AWSObservabilityAdminLogsCentralizationServiceRolePolicy** – CloudWatch Observability Admin uses this role to use telemetry data from other AWS accounts that you specify to create CloudWatch log groups, log streams, and log events in your organization's monitoring account. The SLR only provides the assume role permission to allow the CloudWatch service to assume the role in the monitoring account.

The **AWSObservabilityAdminLogsCentralizationServiceRolePolicy** service-linked role permissions policy allows CloudWatch to complete the following actions:

- `sts:AssumeRole`

  `logs:CreateLogGroup`

  `logs:CreateLogStream`

  `logs:PutLogEvents`

  `kms:Encrypt`

  `kms:Decrypt`

  `kms:GenerateDataKey`

The **AWSObservabilityAdminLogsCentralizationServiceRolePolicy** service-linked role trusts the `logs-centralization.observabilityadmin.amazonaws.com` service to assume the role.

Creating a service-linked role for CloudWatch

You do not need to manually create any of these service-linked roles. The first time you create an alarm in the AWS Management Console, the IAM CLI, or the IAM API, CloudWatch creates

AWSServiceRoleForCloudWatchEvents and **AWSServiceRoleForCloudWatchAlarms_ActionSSM** for you.

The first time that you enable service and topology discovery, Application Signals creates **AWSServiceRoleForCloudWatchApplicationSignals** for you.

When you first enable an account to be a monitoring account for cross-account cross-Region functionality, CloudWatch creates **AWSServiceRoleForCloudWatchCrossAccount** for you.

When you first create an alarm that uses the `DB_PERF_INSIGHTS` metric math function, CloudWatch creates **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** for you.

For more information, see Creating a Service-Linked Role in the *IAM User Guide*.

Editing a service-linked role for CloudWatch

CloudWatch does not allow you to edit the **AWSServiceRoleForCloudWatchEvents**, **AWSServiceRoleForCloudWatchAlarms_ActionSSM**, **AWSServiceRoleForCloudWatchCrossAccount**, or **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** roles. After you create these roles, you cannot change their names because various entities might reference these roles. However, you can edit the description of these roles using IAM.

Editing a service-linked role description (IAM console)

You can use the IAM console to edit the description of a service-linked role.

To edit the description of a service-linked role (console)

1. In the navigation pane of the IAM console, choose **Roles**.
2. Choose the name of the role to modify.
3. To the far right of **Role description**, choose **Edit**.
4. Type a new description in the box, and choose **Save**.

Editing a service-linked role description (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to edit the description of a service-linked role.

To change the description of a service-linked role (AWS CLI)

1. (Optional) To view the current description for a role, use the following commands:

```
$ aws iam get-role --role-name role-name
```

   Use the role name, not the ARN, to refer to roles with the AWS CLI commands. For example, if a role has the following ARN: `arn:aws:iam::123456789012:role/myrole`, you refer to the role as **`myrole`**.
2. To update a service-linked role's description, use the following command:

```
$ aws iam update-role-description --role-name role-name --description description
```

Editing a service-linked role description (IAM API)

You can use the IAM API to edit the description of a service-linked role.

To change the description of a service-linked role (API)

1. (Optional) To view the current description for a role, use the following command:

   GetRole
2. To update a role's description, use the following command:

   UpdateRoleDescription

Deleting a service-linked role for CloudWatch

If you no longer have alarms that automatically stop, terminate, or reboot EC2 instances, we recommend that you delete the AWSServiceRoleForCloudWatchEvents role.

If you not longer have alarms that perform Systems Manager OpsCenter actions, we recommend that you delete the AWSServiceRoleForCloudWatchAlarms_ActionSSM role.

If you delete all alarms that use the `DB_PERF_INSIGHTS` metric math function, we recommend that you delete the **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role.

That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**. Choose the name (not the check box) of the AWSServiceRoleForCloudWatchEvents role.
3. On the **Summary** page for the selected role, choose **Access Advisor** and review the recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether CloudWatch is using the AWSServiceRoleForCloudWatchEvents role, try to delete the role. If the service is using the role, then the deletion fails and you can view the Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

Deleting a service-linked role (IAM console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**. Select the check box next to the name of the role you want to delete, not the name or row itself.
3. For **Role actions**, choose **Delete role**.
4. In the confirmation dialog box, review the service last accessed data, which shows when each of the selected roles last accessed an AWS service. This helps you to confirm whether the role is currently active. To proceed, choose **Yes, Delete**.
5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, the deletion task can succeed or fail after you submit the role for deletion. If the task fails, choose **View details** or

View Resources from the notifications to learn why the deletion failed. If the deletion fails because there are resources in the service that are being used by the role, then the reason for the failure includes a list of resources.

Deleting a service-linked role (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to delete a service-linked role.

To delete a service-linked role (AWS CLI)

1. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `deletion-task-id` from the response to check the status of the deletion task. Type the following command to submit a service-linked role deletion request:

   ```
   $ aws iam delete-service-linked-role --role-name service-linked-role-name
   ```

2. Type the following command to check the status of the deletion task:

   ```
   $ aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
   ```

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Deleting a service-linked role (IAM API)

You can use the IAM API to delete a service-linked role.

To delete a service-linked role (API)

1. To submit a deletion request for a service-linked role, call DeleteServiceLinkedRole. In the request, specify the role name that you want to delete.

   Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.

2. To check the status of the deletion, call GetServiceLinkedRoleDeletionStatus. In the request, specify the `DeletionTaskId`.

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

CloudWatch updates to AWS service-linked roles

View details about updates to AWS managed policies for CloudWatch since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the CloudWatch Document history page.

Change	Description	Date
AWSObservabilityAdminLogsCentralizationServiceRolePolicy – New service-linked role policy.	Added information about the AWSObservabilityAdminLogsCentralizationServiceRolePolicy that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for AWS resources based on telemetry rules.	September 5, 2025
AWSObservabilityAdminTelemetryEnablementServiceRolePolicy – New service-linked role policy.	Added information about the AWSObservabilityAdminTelemetryEnablementServiceRolePolicy that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for AWS resources based on telemetry rules.	July 17, 2025
		March 13, 2025

Change	Description	Date
AWSServiceRoleForCloudWatchApplicationSignals – Update to permissions of service-linked role policy	Updated the CloudWatchApplicationSignalsServiceRolePolicy to exclude time windows from impacting the SLO attainment rate, error budget, and burn rate metrics. CloudWatch can retrieve exclusion windows on behalf of you.	
AWSServiceRoleForObservabilityAdmin – New service-linked role	CloudWatch added this new service-linked role and corresponding managed policy, AWSObservabilityAdminServiceRolePolicy, to support resource and telemetry config discovery for AWS Organizations.	November 26, 2024
AWSServiceRoleForCloudWatchApplicationSignals – Update to permissions of service-linked role policy	CloudWatch add more log groups to the scope of the `logs:StartQuery` and `logs:GetQueryResults` permissions granted by this role.	April 24, 2024

Change	Description	Date
AWSServiceRoleForCloudWatchApplicationSignals – New service-linked role	CloudWatch added this new service-linked role to allow CloudWatch Application Signals to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals.	November 9, 2023
AWSServiceRoleForCloudWatchMetrics_DbPerfInsights – New service-linked role	CloudWatch added this new service-linked role to allow CloudWatch to fetch Performance Insights metrics for alarming and snapshotting. An IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch Performance Insights metrics on your behalf.	September 13, 2023
AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents – New service-linked role	CloudWatch added a new service-linked role to allow CloudWatch to create incidents in AWS Systems Manager Incident Manager.	April 26, 2021
CloudWatch started tracking changes	CloudWatch started tracking changes for its service-linked roles.	April 26, 2021

Using service-linked roles for CloudWatch RUM

CloudWatch RUM uses a AWS Identity and Access Management (IAM) service-linked role. A service-linked role is a unique type of IAM role that is linked directly to RUM. The service-linked role is predefined by RUM and includes all the permissions that the service requires to call other AWS services on your behalf.

RUM defines the permissions of the service-linked role, and unless defined otherwise, only RUM can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the role only after first deleting its related resources. This restriction protects your RUM resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for RUM

RUM uses the service-linked role named **AWSServiceRoleForCloudWatchRUM** – this role allows RUM to send AWS X-Ray trace data into your account, for app monitors that you enable X-Ray tracing for.

The **AWSServiceRoleForCloudWatchRUM** service-linked role trusts the X-Ray service to assume the role. X-Ray sends the trace data to your account.

The **AWSServiceRoleForCloudWatchRUM** service-linked role has an IAM policy attached named **AmazonCloudWatchRUMServiceRolePolicy**. This policy grants permission to CloudWatch RUM to publish monitoring data to other relevant AWS services. It includes permissions that allow RUM to complete the following actions:

- `xray:PutTraceSegments`
- `cloudwatch:PutMetricData`

The complete contents of **AmazonCloudWatchRUMServiceRolePolicy** are as follows.

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "xray:PutTraceSegments"
   ],
   "Resource": [
    "*"
   ]
  },
  {
   "Effect": "Allow",
   "Action": "cloudwatch:PutMetricData",
   "Resource": "*",
   "Condition": {
    "StringLike": {
     "cloudwatch:namespace": [
      "RUM/CustomMetrics/*",
      "AWS/RUM"
     ]
    }
   }
  }
 ]
}
```

Creating a service-linked role for RUM

You do not need to manually create the service-linked role for CloudWatch RUM. The first time that you create an app monitor with X-Ray tracing enabled, or update an app monitor to use X-Ray tracing, RUM creates **AWSServiceRoleForCloudWatchRUM** for you.

For more information, see Creating a Service-Linked Role in the *IAM User Guide*.

Editing a service-linked role for RUM

CloudWatch RUM does not allow you to edit the **AWSServiceRoleForCloudWatchRUM** role. After you create these roles, you cannot change their names because various entities might reference these roles. However, you can edit the description of these roles using IAM.

Editing a service-linked role description (IAM console)

You can use the IAM console to edit the description of a service-linked role.

To edit the description of a service-linked role (console)

1. In the navigation pane of the IAM console, choose **Roles**.
2. Choose the name of the role to modify.
3. To the far right of **Role description**, choose **Edit**.
4. Type a new description in the box, and choose **Save**.

Editing a service-linked role description (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to edit the description of a service-linked role.

To change the description of a service-linked role (AWS CLI)

1. (Optional) To view the current description for a role, use the following commands:

   ```
   $ aws iam get-role --role-name role-name
   ```

   Use the role name, not the ARN, to refer to roles with the AWS CLI commands. For example, if a role has the following ARN: `arn:aws:iam::123456789012:role/myrole`, you refer to the role as **`myrole`**.
2. To update a service-linked role's description, use the following command:

   ```
   $ aws iam update-role-description --role-name role-name --description description
   ```

Editing a service-linked role description (IAM API)

You can use the IAM API to edit the description of a service-linked role.

To change the description of a service-linked role (API)

1. (Optional) To view the current description for a role, use the following command:

   GetRole

2. To update a role's description, use the following command:

   UpdateRoleDescription

Deleting a service-linked role for RUM

If you no longer have app monitors with X-Ray enabled, we recommend that you delete the **AWSServiceRoleForCloudWatchRUM** role.

That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**. Choose the name (not the check box) of the **AWSServiceRoleForCloudWatchRUM** role.
3. On the **Summary** page for the selected role, choose **Access Advisor** and review the recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether RUM is using the **AWSServiceRoleForCloudWatchRUM** role, try to delete the role. If the service is using the role, then the deletion fails and you can view the Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

Deleting a service-linked role (IAM console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**. Select the check box next to the name of the role you want to delete, not the name or row itself.
3. For **Role actions**, choose **Delete role**.
4. In the confirmation dialog box, review the service last accessed data, which shows when each of the selected roles last accessed an AWS service. This helps you to confirm whether the role is currently active. To proceed, choose **Yes, Delete**.
5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, the deletion task can succeed or fail after you submit the role for deletion. If the task fails, choose **View details** or **View Resources** from the notifications to learn why the deletion failed. If the deletion fails because there are resources in the service that are being used by the role, then the reason for the failure includes a list of resources.

Deleting a service-linked role (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to delete a service-linked role.

To delete a service-linked role (AWS CLI)

1. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `deletion-task-id` from the response to check the status of the deletion task. Type the following command to submit a service-linked role deletion request:

```
$ aws iam delete-service-linked-role --role-name service-linked-role-name
```

2. Type the following command to check the status of the deletion task:

```
$ aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
```

The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Deleting a service-linked role (IAM API)

You can use the IAM API to delete a service-linked role.

To delete a service-linked role (API)

1. To submit a deletion request for a service-linked role, call DeleteServiceLinkedRole. In the request, specify the role name that you want to delete.

   Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.
2. To check the status of the deletion, call GetServiceLinkedRoleDeletionStatus. In the request, specify the `DeletionTaskId`.

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Supported Regions for CloudWatch RUM service-linked roles

CloudWatch RUM supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see CloudWatch RUM service endpoints.

Using service-linked roles for CloudWatch Application Insights

CloudWatch Application Insights uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch Application Insights. Service-linked roles are predefined by CloudWatch Application Insights and include all of the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up CloudWatch Application Insights easier because you don't have to manually add the necessary permissions. CloudWatch Application Insights defines the permissions of its service-linked roles, and unless defined otherwise, only CloudWatch Application

Insights can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch Application Insights

CloudWatch Application Insights uses the service-linked role named **AWSServiceRoleForApplicationInsights**. Application Insights uses this role to perform operations such as analyzing the resource groups of the customer, creating CloudFormation stacks to create alarms on metrics, and configuring the CloudWatch Agent on EC2 instances. This service-linked role has an IAM policy attached to it named `CloudwatchApplicationInsightsServiceLinkedRolePolicy`. For updates to this policy, see Application Insights updates to AWS managed policies.

The role permissions policy allows CloudWatch Application Insights to complete the following actions on resources.

```

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the *IAM User Guide*.

Creating a service-linked role for CloudWatch Application Insights

You don't need to manually create a service-linked role. When you create a new Application Insights application in the AWS Management Console, CloudWatch Application Insights creates the service-linked role for you.

If you delete this service-linked role, and then want to create it again, you can use the same process to recreate the role in your account. When you create a new Application Insights application, CloudWatch Application Insights creates the service-linked role for you again.

Editing a service-linked role for CloudWatch Application Insights

CloudWatch Application Insights does not allow you to edit the AWSServiceRoleForApplicationInsights service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the *IAM User Guide*.

Deleting a service-linked role for CloudWatch Application Insights

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you avoid having an unused entity that is not actively monitored or maintained. However, you must delete all applications in Application Insights before you can manually delete the role.

> **Note**
>
> If the CloudWatch Application Insights service is using the role when you try to delete the resources, the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete CloudWatch Application Insights resources used by the AWSServiceRoleForApplicationInsights

- Delete all of your CloudWatch Application Insights applications. For more information, see "Deleting Your Application(s)" in the CloudWatch Application Insights User Guide.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForApplicationInsights service-linked role. For more information, see Deleting a Service-Linked Role in the *IAM User Guide*.

Supported Regions for CloudWatch Application Insights service-linked roles

CloudWatch Application Insights supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see CloudWatch Application Insights Regions and Endpoints.

AWS managed policies for Amazon CloudWatch Application Insights

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

AWS managed policy: CloudWatchApplicationInsightsFullAccess

You can attach the `CloudWatchApplicationInsightsFullAccess` policy to your IAM identities.

This policy grants administrative permissions that allow full access to Application Insights functionality.

Permissions details

This policy includes the following permissions.

- `applicationinsights` – Allows full access to Application Insights functionality.
- `iam` – Allows Application Insights to create the service-linked role, AWSServiceRoleForApplicationInsights. This is required so that Application Insights can perform operations such as analyze the resource groups of a customer, create CloudFormation stacks to create alarms on metrics, and configure the CloudWatch Agent on EC2 instances. For more information, see Using service-linked roles for CloudWatch Application Insights.

    {
      "Effect": "Allow",
      "Action": [
        "iam:CreateServiceLinkedRole"
      ],
      "Resource": [
        "arn:aws:iam::*:role/aws-service-role/application-insights.amazonaws.com/
AWSServiceRoleForApplicationInsights"
      ],
      "Condition": {
        "StringEquals": {
          "iam:AWSServiceName": "application-insights.amazonaws.com"
        }
      }
    }
  ]
}
```

AWS managed policy: CloudWatchApplicationInsightsReadOnlyAccess

You can attach the `CloudWatchApplicationInsightsReadOnlyAccess` policy to your IAM identities.

This policy grants administrative permissions that allow read-only access to all Application Insights functionality.

Permissions details

This policy includes the following permissions.

- `applicationinsights` – Allows read-only access to Application Insights functionality.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "applicationinsights:Describe*",
                "applicationinsights:List*"
            ],
            "Resource": "*"
        }
    ]
}
```

AWS managed policy: CloudwatchApplicationInsightsServiceLinkedRolePolicy

You can't attach CloudwatchApplicationInsightsServiceLinkedRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows Application Insights to monitor customer

resources. For more information, see Using service-linked roles for CloudWatch Application Insights.

Application Insights updates to AWS managed policies

View details about updates to AWS managed policies for Application Insights since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Application Insights Document history page.

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added a new permission. The policy change allows Amazon CloudWatch Application Insights to enable and disable termination protection on CloudFormation stacks to manage SSM resources used to install and configure CloudWatch agents.	July 25, 2024
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to list CloudFormation stacks. These permissions are required for Amazon CloudWatch Application Insights to analyze and monitor AWS resources nested in the CloudFormation stack.	April 24, 2023

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to get list of Amazon VPC and Route 53 resources. These permissions are required for Amazon CloudWatch Application Insights to automatically set up best practice network monitoring with Amazon CloudWatch.	January 23, 2023
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to get SSM command invocation results. These permissions are required for Amazon CloudWatch Application Insights to automatically detect and monitor workloads running on Amazon EC2 instances.	December 19, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe Amazon VPC and Route 53 resources. These permissions are required for Amazon CloudWatch Application Insights to read customer Amazon VPC and Route 53 resource configurations, and to help customers automatically set up best practice network monitoring with Amazon CloudWatch.	December 19, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe EFS resources. These permissions are required for Amazon CloudWatch Application Insights to read Amazon EFS customer resource configurations, and to help customers automatically set up best practices for EFS monitoring with CloudWatch.	October 3, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe the EFS file system. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	October 3, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to retrieve information about FSx resources. These permissions are required for Amazon CloudWatch Application Insights to monitor workloads by retrieving sufficient information about the underlying FSx volumes.	September 12, 2022
AWS managed policy: CloudWatchApplicationInsightsFullAccess – Update to an existing policy	Application Insights added a new permission to describe log groups. This permissions is required for Amazon CloudWatch Application Insights to ensure that the correct permissions for monitoring log groups are in an account when creating a new application.	January 24, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to create and delete CloudWatch Log Subscription Filters. These permissions are required for Amazon CloudWatch Application Insights to create Subscription Filters to facilitate log monitoring of resources within configured applications.	January 24, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe target groups and target health for Elastic Load Balancers. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	November 4, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to run the `AmazonCloudWatch-ManageAgent` SSM document on Amazon EC2 instances. This permissions is required for Amazon CloudWatch Application Insights to clean up CloudWatch agent configuration files created by Application Insights.	September 30, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to support account-based applicati on monitoring to onboard and monitor all supported resources in your account. These permissions are required for Amazon CloudWatch Applicati on Insights to query, tag resources, and create groups for these resources. Application Insights added new permissions to support monitoring of SNS topics. These permissions are required for Amazon CloudWatch Application Insights to gather metadata from SNS resources to configure monitoring for SNS topics.	September 15, 2021

Change	Description	Date
AWS managed policy: CloudWatchApplicationInsightsFullAccess – Update to an existing policy	Application Insights added new permissions to describe and list supported resources. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	September 15, 2021
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe FSx resources. These permissions are required for Amazon CloudWatch Application Insights to read customer FSx resource configurations, and to help customers automatically set up best practice FSx monitoring with CloudWatch.	August 31, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe and list ECS and EKS service resources. This permission is required for Amazon CloudWatch Application Insights to read customer container resources configuration, and to help customers automatically set up best practice container monitoring with CloudWatch.	May 18, 2021
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to allow OpsCenter to tag OpsItems using the `ssm:AddTagsToResource` action on resources with the `opsitem` resource type. This permission is required by OpsCenter. Amazon CloudWatch Application Insights creates OpsItems so that the customer can resolve problems using AWS SSM OpsCenter.	April 13, 2021
Application Insights started tracking changes	Application Insights started tracking changes for its AWS managed policies.	April 13, 2021

Amazon CloudWatch permissions reference

The following table lists each CloudWatch API operation and the corresponding actions for which you can grant permissions to perform the action. You specify the actions in the policy's `Action` field, and you specify a wildcard character (*) as the resource value in the policy's `Resource` field.

You can use AWS-wide condition keys in your CloudWatch policies to express conditions. For a complete list of AWS-wide keys, see AWS Global and IAM Condition Context Keys in the *IAM User Guide*.

> **Note**
>
> To specify an action, use the `cloudwatch:` prefix followed by the API operation name. For example: `cloudwatch:GetMetricData`, `cloudwatch:ListMetrics`, or `cloudwatch:*` (for all CloudWatch actions).

Topics

- CloudWatch API operations and required permissions for actions
- CloudWatch Application Signals API operations and required permissions for actions
- CloudWatch Contributor Insights API operations and required permissions for actions
- CloudWatch Events API operations and required permissions for actions
- CloudWatch Logs API operations and required permissions for actions
- Amazon EC2 API operations and required permissions for actions
- Amazon EC2 Auto Scaling API operations and required permissions for actions

CloudWatch API operations and required permissions for actions

CloudWatch API operations	Required permissions (API actions)
DeleteAlarms	`cloudwatch:DeleteAlarms` Required to delete an alarm.
DeleteDashboards	`cloudwatch:DeleteDashboards`

CloudWatch API operations	Required permissions (API actions)
	Required to delete a dashboard.
DeleteMetricStream	`cloudwatch:DeleteMetricStream` Required to delete a metric stream.
DescribeAlarmHistory	`cloudwatch:DescribeAlarmHistory` Required to view alarm history. To retrieve information about composite alarms, your `cloudwatch:DescribeAlarmHistory` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:DescribeAlarmHistory` permission has a narrower scope.
DescribeAlarms	`cloudwatch:DescribeAlarms` Required to retrieve information about alarms. To retrieve information about composite alarms, your `cloudwatch:DescribeAlarms` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:DescribeAlarms` permission has a narrower scope.
DescribeAlarmsForMetric	`cloudwatch:DescribeAlarmsForMetric` Required to view alarms for a metric.

CloudWatch API operations	Required permissions (API actions)
DisableAlarmActions	`cloudwatch:DisableAlarmActions` Required to disable an alarm action.
EnableAlarmActions	`cloudwatch:EnableAlarmActions` Required to enable an alarm action.
GetDashboard	`cloudwatch:GetDashboard` Required to display data about existing dashboards.
GetMetricData	`cloudwatch:GetMetricData` Required to graph metric data in the CloudWatch console, to retrieve large batches of metric data, and perform metric math on that data.
GetMetricStatistics	`cloudwatch:GetMetricStatistics` Required to view graphs in other parts of the CloudWatch console and in dashboard widgets.
GetMetricStream	`cloudwatch:GetMetricStream` Required to view information about a metric stream.

CloudWatch API operations	Required permissions (API actions)
GetMetricWidgetImage	`cloudwatch:GetMetricWidgetImage` Required to retrieve a snapshot graph of one or more CloudWatch metrics as a bitmap image.
ListDashboards	`cloudwatch:ListDashboards` Required to view the list of CloudWatch dashboards in your account.
ListEntitiesForMetric (CloudWatch console-only permission)	`cloudwatch:ListEntitiesForMetric` Required to find the entities associated with a metric. Required to explore related telemetry within the CloudWatch console.
ListMetrics	`cloudwatch:ListMetrics` Required to view or search metric names within the CloudWatch console and in the CLI. Required to select metrics on dashboard widgets.
ListMetricStreams	`cloudwatch:ListMetricStreams` Required to view or search the list of metric streams in the account.

CloudWatch API operations	Required permissions (API actions)
PutCompositeAlarm	`cloudwatch:PutCompositeAlarm` Required to create a composite alarm. To create a composite alarm, your `cloudwatch:PutCompositeAlarm` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:PutCompositeAlarm` permission has a narrower scope.
PutDashboard	`cloudwatch:PutDashboard` Required to create a dashboard or update an existing dashboard.
PutMetricAlarm	`cloudwatch:PutMetricAlarm` Required to create or update an alarm.
PutMetricData	`cloudwatch:PutMetricData` Required to create metrics.
PutMetricStream	`cloudwatch:PutMetricStream` Required to create a metric stream.
SetAlarmState	`cloudwatch:SetAlarmState` Required to manually set an alarm's state.

CloudWatch API operations	Required permissions (API actions)
StartMetricStreams	`cloudwatch:StartMetricStreams` Required to start the flow of metrics in a metric stream.
StopMetricStreams	`cloudwatch:StopMetricStreams` Required to temporarily stop the flow of metrics in a metric stream.
TagResource	`cloudwatch:TagResource` Required to add or update tags on CloudWatch resources such as alarms and Contributor Insights rules.
UntagResource	`cloudwatch:UntagResource` Required to remove tags from CloudWatch resources .

CloudWatch Application Signals API operations and required permissions for actions

CloudWatch Application Signals API operations	Required permissions (API actions)
BatchGetServiceLevelObjectiveBudgetReport	`application-signals:BatchGetServiceLevelObjectiveBudgetReport`

CloudWatch Application Signals API operations	Required permissions (API actions)
	Required to retrieve service level objective budget reports.
CreateServiceLevelObjective	`application-signals:CreateServiceLevelObjective` Required to create a service level objective (SLO).
DeleteServiceLevelObjective	`application-signals:DeleteServiceLevelObjective` Required to delete a service level objective (SLO).
GetService	`application-signals:GetService` Required to retrieve information about a service discovered by Application Signals.
GetServiceLevelObjective	`application-signals:GetServiceLevelObjective` Required to retrieve information about a service level objective (SLO).
ListObservedEntities	`application-signals:ListObservedEntities` Grants permission to list entities that are associated with other entities.

CloudWatch Application Signals API operations	Required permissions (API actions)
ListServiceDependencies	`application-signals:ListServiceDependencies` Required to retrieve a list of service dependencies of a service that you specify. This service and the dependencies were discovered by Application Signals.
ListServiceDependents	`application-signals:ListServiceDependents` Required to retrieve a list of dependents that invoked a service that you specify. This service and the dependents were discovered by Application Signals.
ListServiceLevelObjectives	`application-signals:ListServiceLevelObjectives` Required to retrieve a list of service level objectives (SLOs) in the account.
ListServiceOperations	`application-signals:ListServiceOperations` Required to retrieve a list of service operations of a service that you specify. This service and the dependencies were discovered by Application Signals.

CloudWatch Application Signals API operations	Required permissions (API actions)
ListServices	`application-signals:ListServices` Required to retrieve a list of services discovered by Application Signals.
ListTagsForResource	`application-signals:ListTagsForResource` Required to retrieve a list of the tags associated with a resource.
StartDiscovery	`application-signals:StartDiscovery` Required to be able to enable Application Signals in the account and create the required service-linked role.
TagResource	`application-signals:TagResource` Required to be able to add tags to resources.
UntagResource	`application-signals:UntagResource` Required to be able to remove tags from resources.

CloudWatch Application Signals API operations	Required permissions (API actions)
UpdateServiceLevelObjective	`application-signals:UpdateServiceLevelObjective` Required to update an existing service level objective

CloudWatch Contributor Insights API operations and required permissions for actions

> **Important**
>
> When you grant a user the `cloudwatch:PutInsightRule` permission, by default that user can create a rule that evaluates any log group in CloudWatch Logs. You can add IAM policy conditions that limit these permissions for a user to include and exclude specific log groups. For more information, see Using condition keys to limit Contributor Insights users' access to log groups.

CloudWatch Contributor Insights API operations	Required permissions (API actions)
DeleteInsightRules	`cloudwatch:DeleteInsightRules` Required to delete Contributor Insights rules.
DescribeInsightRules	`cloudwatch:DescribeInsightRules` Required to view the Contributor Insights rules in your account.
EnableInsightRules	`cloudwatch:EnableInsightRules`

CloudWatch Contributor Insights API operations	Required permissions (API actions)
	Required to enable Contributor Insights rules.
GetInsightRuleReport	`cloudwatch:GetInsightRuleReport` Required to retrieve time series data and other statistics collectd by Contributor Insights rules.
PutInsightRule	`cloudwatch:PutInsightRule` Required to create Contributor Insights rules. See the **Important** note at the beginning of this table.

CloudWatch Events API operations and required permissions for actions

CloudWatch Events API operations	Required permissions (API actions)
DeleteRule	`events:DeleteRule` Required to delete a rule.
DescribeRule	`events:DescribeRule` Required to list the details about a rule.
DisableRule	`events:DisableRule` Required to disable a rule.
EnableRule	`events:EnableRule`

CloudWatch Events API operations	Required permissions (API actions)
	Required to enable a rule.
ListRuleNamesByTarget	`events:ListRuleNamesByTarget` Required to list rules associated with a target.
ListRules	`events:ListRules` Required to list all rules in your account.
ListTargetsByRule	`events:ListTargetsByRule` Required to list all targets associated with a rule.
PutEvents	`events:PutEvents` Required to add custom events that can be matched to rules.
PutRule	`events:PutRule` Required to create or update a rule.
PutTargets	`events:PutTargets` Required to add targets to a rule.
RemoveTargets	`events:RemoveTargets` Required to remove a target from a rule.

CloudWatch Events API operations	Required permissions (API actions)
TestEventPattern	`events:TestEventPattern` Required to test an event pattern against a given event.

CloudWatch Logs API operations and required permissions for actions

> **Note**
>
> CloudWatch Logs permissions can be found in the CloudWatch Logs user guide.

Amazon EC2 API operations and required permissions for actions

Amazon EC2 API operations	Required permissions (API actions)
DescribeInstanceStatus	`ec2:DescribeInstanceStatus` Required to view EC2 instance status details.
DescribeInstances	`ec2:DescribeInstances` Required to view EC2 instance details.
RebootInstances	`ec2:RebootInstances` Required to reboot an EC2 instance.
StopInstances	`ec2:StopInstances` Required to stop an EC2 instance.
TerminateInstances	`ec2:TerminateInstances`

Amazon EC2 API operations	Required permissions (API actions)
	Required to terminate an EC2 instance.

Amazon EC2 Auto Scaling API operations and required permissions for actions

Amazon EC2 Auto Scaling API operations	Required permissions (API actions)
Scaling	`autoscaling:Scaling` Required to scale an Auto Scaling group.
Trigger	`autoscaling:Trigger` Required to trigger an Auto Scaling action.

Compliance validation for Amazon CloudWatch

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security Compliance & Governance – These solution implementation guides discuss architectural considerations and provide steps for deploying security and compliance features.
- HIPAA Eligible Services Reference – Lists HIPAA eligible services. Not all AWS services are HIPAA eligible.
- AWS Compliance Resources – This collection of workbooks and guides might apply to your industry and location.

- AWS Customer Compliance Guides – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).
- Evaluating Resources with Rules in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
- Amazon GuardDuty – This AWS service detects potential threats to your AWS accounts, workloads, containers, and data by monitoring your environment for suspicious and malicious activities. GuardDuty can help you address various compliance requirements, like PCI DSS, by meeting intrusion detection requirements mandated by certain compliance frameworks.
- AWS Audit Manager – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

Resilience in Amazon CloudWatch

The AWS global infrastructure is built around AWS Regions and Availability Zones. Regions provide multiple physically separated and isolated Availability Zones, which are connected through low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Infrastructure security in Amazon CloudWatch

As a managed service, Amazon CloudWatch is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access CloudWatch through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

Network isolation

A virtual private cloud (VPC) is a virtual network in your own logically isolated area in the Amazon Web Services Cloud. A subnet is a range of IP addresses in a VPC. You can deploy a variety of AWS resources in the subnets of your VPCs. For example, you can deploy Amazon EC2 instances, EMR clusters, and DynamoDB tables in subnets. For more information, see the Amazon VPC User Guide.

To enable CloudWatch to communicate with resources in a VPC without going through the public internet, use AWS PrivateLink. For more information, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints.

A private subnet is a subnet with no default route to the public internet. Deploying an AWS resource in a private subnet does not prevent Amazon CloudWatch from collecting built-in metrics from the resource.

If you need to publish custom metrics from an AWS resource in a private subnet, you can do so using a proxy server. The proxy server forwards those HTTPS requests to the public API endpoints for CloudWatch.

AWS Security Hub

Monitor your usage of CloudWatch as it relates to security best practices by using AWS Security Hub. Security Hub uses *security controls* to evaluate resource configurations and *security standards* to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate CloudWatch resources, see Amazon CloudWatch controls in the AWS Security Hub User Guide.

Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints

If you use Amazon Virtual Private Cloud (Amazon VPC) to host your AWS resources, you can establish a private connection between your VPC, CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring features. You can use these connections to enable these services to communicate with resources in your VPC without going through the public internet.

Amazon VPC is an AWS service that you can use to launch AWS resources in a virtual network that you define. With a VPC, you have control over your network settings, such the IP address range, subnets, route tables, and network gateways. To connect your VPC to CloudWatch services, you define an *interface VPC endpoint* for your VPC. The endpoint provides reliable, scalable connectivity to CloudWatch and supported CloudWatch services without requiring an internet gateway, network address translation (NAT) instance, or VPN connection. For more information, see What is Amazon VPC in the *Amazon VPC User Guide*.

Interface VPC endpoints are powered by AWS PrivateLink, an AWS technology that enables private communication between AWS services using an elastic network interface with private IP addresses. For more information, see the following blog post: New – AWS PrivateLink for AWS Services

The following steps are for users of Amazon VPC. For more information, see Getting Started in the *Amazon VPC User Guide*.

CloudWatch VPC endpoints

CloudWatch currently supports VPC endpoints, including IPv6-only and dual stack enabled endpoints, in all AWS Regions, including the AWS GovCloud (US) Regions. For information on endpoints URL, see CloudWatch endpoints and quotas .

Creating a VPC endpoint for CloudWatch

To start using CloudWatch with your VPC, create an interface VPC endpoint for CloudWatch. The service name to choose is `com.amazonaws.`*`region`*`.monitoring`. For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You do not need to change the settings for CloudWatch. CloudWatch calls other AWS services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, if you create an interface VPC endpoint for CloudWatch, and you already have metrics

flowing to CloudWatch from resources located on your VPC, these metrics begin flowing through the interface VPC endpoint by default.

Controlling access to your CloudWatch VPC endpoint

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. If you don't attach a policy when you create an endpoint, Amazon VPC attaches a default policy for you that allows full access to the service. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

Endpoint policies must be written in JSON format.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy for CloudWatch. This policy allows users connecting to CloudWatch through the VPC to send metric data to CloudWatch and prevents them from performing other CloudWatch actions.

```
{
  "Statement": [
    {
      "Sid": "PutOnly",
      "Principal": "*",
      "Action": [
        "cloudwatch:PutMetricData"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

To edit the VPC endpoint policy for CloudWatch

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for CloudWatch, choose **Create endpoint**. Select **com.amazonaws.*region*.monitoring**, and then choose **Create endpoint**.

4. Select the **com.amazonaws.*region*.monitoring** endpoint, and then choose the **Policy** tab.
5. Choose **Edit policy**, and then make your changes.

CloudWatch Synthetics VPC endpoint

CloudWatch Synthetics currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- South America (São Paulo)

Creating a VPC endpoint for CloudWatch Synthetics

To start using CloudWatch Synthetics with your VPC, create an interface VPC endpoint for CloudWatch Synthetics. The service name to choose is `com.amazonaws.region.synthetics`. For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You do not need to change the settings for CloudWatch Synthetics. CloudWatch Synthetics communicates with other AWS services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, if you create an interface VPC endpoint for

CloudWatch Synthetics, and you already have an interface endpoint for Amazon S3, CloudWatch Synthetics begins communicating with Amazon S3 through the interface VPC endpoint by default.

Controlling access to your CloudWatch Synthetics VPC endpoint

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. If you don't attach a policy when you create an endpoint, we attach a default policy for you that allows full access to the service. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

Endpoint policies affect canaries that are managed privately by VPC. They are not needed for canaries that run on private subnets.

Endpoint policies must be written in JSON format.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy for CloudWatch Synthetics. This policy enables users connecting to CloudWatch Synthetics through the VPC to view information about canaries and their runs, but not to create, modify, or delete canaries.

```
{
    "Statement": [
        {
            "Action": [
                "synthetics:DescribeCanaries",
                "synthetics:GetCanaryRuns"
            ],
            "Effect": "Allow",
            "Resource": "*",
            "Principal": "*"
        }
    ]
}
```

To edit the VPC endpoint policy for CloudWatch Synthetics

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.

3. If you have not already created the endpoint for CloudWatch Synthetics, choose **Create endpoint**. Select **com.amazonaws.*region*.synthetics** and then choose **Create endpoint**.
4. Select the **com.amazonaws.*region*.synthetics** endpoint, and then choose the **Policy** tab.
5. Choose **Edit policy**, and then make your changes.

CloudWatch Network Monitoring feature VPC endpoints

CloudWatch Network Monitoring includes the following features: Network Flow Monitor, Internet Monitor, and Network Synthetic Monitor. These features each support VPC endpoints in the AWS Regions where the Network Monitoring feature is supported.

To see a list of supported Regions for each Network Monitoring feature, see the following topics:

- **Network Flow Monitor:** Supported AWS Regions for Network Flow Monitor
- **Internet Monitor:** Supported AWS Regions for Internet Monitor
- **Network Synthetic Monitor:** Supported AWS Regions for Network Synthetic Monitor

Creating a VPC endpoint for a CloudWatch Network Monitoring feature

To start using CloudWatch Network Monitoring features with your VPC, create an interface VPC endpoint for the feature that you want to use. For Network Monitoring, the following service names are available:

- `com.amazonaws.region.networkflowmonitor`
- `com.amazonaws.region.networkflowmonitorreports`
- `com.amazonaws.region.internetmonitor`
- `com.amazonaws.region.internetmonitor-fips`
- `com.amazonaws.region.networkmonitor`

For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You don't need to change the settings for Network Monitoring services. Network Monitoring services communicate with other AWS services using either public endpoints or private interface VPC endpoints, whichever are being used. For example, if you create an interface VPC endpoint for a Network Monitoring service, and you already have metrics flowing to the service from resources located on your VPC, the metrics begin flowing through the interface VPC endpoint by default.

Controlling access to your CloudWatch Network Monitoring feature VPC endpoints

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

If you don't attach a policy when you create an endpoint, Amazon VPC attaches a default policy for you that allows full access and does not restrict access to a specific service. For additional security, you can attach a policy to the endpoint to specifically limit access to the feature. For example, for Internet Monitor, you could allow full access to just Internet Monitor by attaching the AWS managed policy that enables full access to the feature, CloudWatchInternetMonitorFullAccess. Or, you can further limit permissions to just specific actions for the endpoint.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy that you could create for Network Flow Monitor to limit actions for the endpoint. This policy allows requests to Network Flow Monitor through the VPC to use only the `Publish` action, which enables requests to publish metrics to Network Flow Monitor backend ingestion.

```
{
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": "*",
            "Action": "networkflowmonitor:Publish",
            "Resource": "*"
        }
    ]
}
```

If you want to use a specific VPC endpoint policy with an interface VPC endpoint for a Network Monitoring feature, use steps similar to the following example for adding a policy for Network Flow Monitor.

To edit a VPC endpoint policy for Network Flow Monitor

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for Internet Monitor, choose **Create endpoint**.
4. Select **com.amazonaws.*region*.networkflowmonitor**, and then choose **Create endpoint**.
5. Select the **com.amazonaws.*region*.networkflowmonitor** endpoint, and then choose the **Policy** tab.
6. Choose **Edit policy**, and then make your changes.

Security considerations for Synthetics canaries

The following sections explain security issues that you should consider when creating and running canaries in Synthetics.

Use secure connections

Because canary code and the results from canary test runs can contain sensitive information, do not have your canary connect to endpoints over unencrypted connections. Always use encrypted connections, such as those that begin with `https://`.

Canary naming considerations

The Amazon Resource Name (ARN) of a canary is included in the user-agent header as a part of outbound calls made from the Puppeteer-driven Chromium browser that is included as a part of the CloudWatch Synthetics wrapper library. This helps identify CloudWatch Synthetics canary traffic and relate it back to the canaries that are making calls.

The canary ARN includes the canary name. Choose canary names that do not reveal proprietary information.

Additionally, be sure to point your canaries only at websites and endpoints that you control.

Secrets and sensitive information in canary code

If you pass your canary code directly into the canary using a zip file, the contents of the script can be seen in AWS CloudTrail logs.

If you have sensitive information or secrets (such as access keys or database credentials) in a canary script, we strongly recommend that you store the script as a versioned object in Amazon S3 and pass the Amazon S3 location into the canary, instead of passing the canary code by a zip file.

If you do use a zip file to pass the canary script, we strongly recommend that you don't include secrets or sensitive information in your canary source code. For more information about how to use AWS Secrets Manager to help keep your secrets safe, see What is AWS Secrets Manager?.

Permissions considerations

We recommend that you restrict access to resources that are created or used by CloudWatch Synthetics. Use tight permissions on the Amazon S3 buckets where canaries store test run results and other artifacts, such as logs and screenshots.

Similarly, keep tight permissions on the locations where your canary source code is stored, so that no user accidentally or maliciously deletes the Lambda layers or Lambda functions used for the canary.

To help make sure you run the canary code you intend, you can use object versioning on the Amazon S3 bucket where your canary code is stored. Then when you specify this code to run as a canary, you can include the object `versionId` as part of the path, as in the following examples.

```
https://bucket.s3.amazonaws.com/path/object.zip?versionId=version-id
https://s3.amazonaws.com/bucket/path/object.zip?versionId=version-id
https://bucket.s3-region.amazonaws.com/path/object.zip?versionId=version-id
```

Stack traces and exception messages

By default, CloudWatch Synthetics canaries capture any exception thrown by your canary script, no matter whether the script is custom or is from a blueprint. CloudWatch Synthetics logs both the exception message and the stack trace to three locations:

- Back into the CloudWatch Synthetics service to speed up debugging when you describe test runs
- Into CloudWatch Logs according to the configuration that your Lambda functions are created with
- Into the Synthetics log file, which is a plaintext file that is uploaded to the Amazon S3 location specified by the value you set for the `resultsLocation` of the canary

If you want to send and store less information, you can capture exceptions before they return to the CloudWatch Synthetics wrapper library.

You can also have request URLs in your errors. CloudWatch Synthetics scans for any URLs in the error thrown by your script and redacts restricted URL parameters from them based on the

restrictedUrlParameters configuration. If you are logging error messages in your script, you can use getSanitizedErrorMessage to redact URLs before logging.

Scope your IAM roles narrowly

We recommend that you do not configure your canary to visit potentially malicious URLs or endpoints. Pointing your Canary to untrusted or unknown websites or endpoints could expose your Lambda function code to malicious user's scripts. Assuming a malicious website can break out of Chromium, it could have access to your Lambda code in a similar way to if you connected to it using an internet browser.

Run your Lambda function with an IAM execution role that has scoped-down permissions. This way, if your Lambda function is compromised by a malicious script, it is limited in the actions it can take when running as your canary's AWS account.

When you use the CloudWatch console to create a canary, it is created with a scoped-down IAM execution role.

Sensitive data redaction

CloudWatch Synthetics captures URLs, status code, failure reason (if any), and headers and bodies of requests and responses. This enables a canary user to understand, monitor, and debug canaries.

The configurations described in the following sections can be set at any point in canary execution. You can also choose to apply different configurations to different synthetics steps.

Request URLs

By default, CloudWatch Synthetics logs request URLs, status codes, and the status reason for each URL in canary logs. Request URLs can also appear in canary execution reports, HAR files, and so on. Your request URL might contain sensitive query parameters, such as access tokens or passwords. You can redact sensitive information from being logged by CloudWatch Synthetics.

To redact sensitive information, set the configuration property **restrictedUrlParameters**. For more information, see SyntheticsConfiguration class. This causes CloudWatch Synthetics to redact URL parameters, including path and query parameter values, based on **restrictedUrlParameters** before logging. If you are logging URLs in your script, you can use getSanitizedUrl(url, stepConfig = null) to redact URLs before logging. For more information, see SyntheticsLogHelper class.

Headers

By default, CloudWatch Synthetics doesn't log request/response headers. For UI canaries, this is the default behavior for canaries using runtime version `syn-nodejs-puppeteer-3.2` and later.

If your headers don't contain sensitive information, you can enable headers in HAR file and HTTP reports by setting the **includeRequestHeaders** and **includeResponseHeaders** properties to `true`. You can enable all headers but choose to restrict values of sensitive header keys. For example, you can choose to only redact `Authorization` headers from artifacts produced by canaries.

Request and response body

By default, CloudWatch Synthetics doesn't log the request/response body in canary logs or reports. This information is particularly useful for API canaries. Synthetics captures all HTTP requests and can show headers, request and response bodies. For more information, see executeHttpStep(stepName, requestOptions, [callback], [stepConfig]). You can choose to enable request/response body by setting the **includeRequestBody** and **includeResponseBody** properties to `true`.

Logging Amazon CloudWatch API and console operations with AWS CloudTrail

Amazon CloudWatch, CloudWatch Synthetics, CloudWatch RUM, Amazon Q Developer operational investigations, Network Flow Monitor, and Internet Monitor are integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures API calls made by or on behalf of your AWS account. The captured calls include calls from the CloudWatch console and code calls to CloudWatch API operations. Using the information collected by CloudTrail, you can determine the request that was made to CloudWatch, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see Working with CloudTrail Event history in the *AWS CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a CloudTrail Lake event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see Creating a

trail for your AWS account and Creating a trail for an organization in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see AWS CloudTrail Pricing. For information about Amazon S3 pricing, see Amazon S3 Pricing.

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to Apache ORC format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying advanced event selectors. The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see Working with AWS CloudTrail Lake in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the pricing option you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

Note

For information about CloudWatch Logs API calls that are logged in CloudTrail, see CloudWatch Logs information in CloudTrail.

CloudWatch information in CloudTrail

CloudWatch supports logging the following actions as events in CloudTrail log files:

- DeleteAlarmActions
- DeleteAnomalyDetector
- DeleteDashboards
- DeleteInsightRules
- DeleteMetricStream
- DescribeAlarmHistory
- DescribeAlarms
- DescribeAlarmsForMetric
- DescribeAnomalyDetectors
- DescribeInsightRules
- DisableAlarmActions
- DisableInsightRules
- EnableAlarmActions
- EnableInsightRules
- GetDashboard
- GetInsightRuleReport
- GetMetricStream

- ListDashboards
- ListManagedInsightRules
- ListMetricStreams
- ListTagsForResource
- PutAnomalyDetector
- PutCompositeAlarm
- PutDashboard
- PutInsightRule
- PutManagedInsightRules
- PutMetricAlarm
- PutMetricStream
- SetAlarmState
- StartMetricStreams
- StopMetricStreams
- TagResource
- UntagResource

Example: CloudWatch log file entries

The following example shows a CloudTrail log entry that demonstrates the `PutMetricAlarm` action.

```
{
    "Records": [{
        "eventVersion": "1.01",
        "userIdentity": {
            "type": "Root",
            "principalId": "EX_PRINCIPAL_ID",
            "arn": "arn:aws:iam::123456789012:root",
            "accountId": "123456789012",
            "accessKeyId": "EXAMPLE_KEY_ID"
        },
        "eventTime": "2014-03-23T21:50:34Z",
        "eventSource": "monitoring.amazonaws.com",
        "eventName": "PutMetricAlarm",
        "awsRegion": "us-east-1",
```

```
        "sourceIPAddress": "127.0.0.1",
        "userAgent": "aws-sdk-ruby2/2.0.0.rc4 ruby/1.9.3 x86_64-linux Seahorse/0.1.0",
        "requestParameters": {
            "threshold": 50.0,
            "period": 60,
            "metricName": "CloudTrail Test",
            "evaluationPeriods": 3,
            "comparisonOperator": "GreaterThanThreshold",
            "namespace": "AWS/CloudWatch",
            "alarmName": "CloudTrail Test Alarm",
            "statistic": "Sum"
        },
        "responseElements": null,
        "requestID": "29184022-b2d5-11e3-a63d-9b463e6d0ff0",
        "eventID": "b096d5b7-dcf2-4399-998b-5a53eca76a27"
    },
    ..additional entries
  ]
  }
```

The following log file entry shows that a user called the CloudWatch Events `PutRule` action.

```
{
         "eventVersion":"1.03",
         "userIdentity":{
            "type":"Root",
            "principalId":"123456789012",
            "arn":"arn:aws:iam::123456789012:root",
            "accountId":"123456789012",
            "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
            "sessionContext":{
               "attributes":{
                  "mfaAuthenticated":"false",
                  "creationDate":"2015-11-17T23:56:15Z"
               }
            }
         },
         "eventTime":"2015-11-18T00:11:28Z",
         "eventSource":"events.amazonaws.com",
         "eventName":"PutRule",
         "awsRegion":"us-east-1",
         "sourceIPAddress":"AWS Internal",
         "userAgent":"AWS CloudWatch Console",
```

```
         "requestParameters":{
            "description":"",
            "name":"cttest2",
            "state":"ENABLED",
            "eventPattern":"{\"source\":[\"aws.ec2\"],\"detail-type\":[\"EC2 Instance
 State-change Notification\"]}",
            "scheduleExpression":""
         },
         "responseElements":{
            "ruleArn":"arn:aws:events:us-east-1:123456789012:rule/cttest2"
         },
         "requestID":"e9caf887-8d88-11e5-a331-3332aa445952",
         "eventID":"49d14f36-6450-44a5-a501-b0fdcdfaeb98",
         "eventType":"AwsApiCall",
         "apiVersion":"2015-10-07",
         "recipientAccountId":"123456789012"
}
```

The following log file entry shows that a user called the CloudWatch Logs `CreateExportTask` action.

```
{
        "eventVersion": "1.03",
        "userIdentity": {
            "type": "IAMUser",
            "principalId": "EX_PRINCIPAL_ID",
            "arn": "arn:aws:iam::123456789012:user/someuser",
            "accountId": "123456789012",
            "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
            "userName": "someuser"
        },
        "eventTime": "2016-02-08T06:35:14Z",
        "eventSource": "logs.amazonaws.com",
        "eventName": "CreateExportTask",
        "awsRegion": "us-east-1",
        "sourceIPAddress": "127.0.0.1",
        "userAgent": "aws-sdk-ruby2/2.0.0.rc4 ruby/1.9.3 x86_64-linux Seahorse/0.1.0",
        "requestParameters": {
            "destination": "yourdestination",
            "logGroupName": "yourloggroup",
            "to": 123456789012,
            "from": 0,
            "taskName": "yourtask"
```

```
        },
        "responseElements": {
            "taskId": "15e5e534-9548-44ab-a221-64d9d2b27b9b"
        },
        "requestID": "1cd74c1c-ce2e-12e6-99a9-8dbb26bd06c9",
        "eventID": "fd072859-bd7c-4865-9e76-8e364e89307c",
        "eventType": "AwsApiCall",
        "apiVersion": "20140328",
        "recipientAccountId": "123456789012"
}
```

CloudWatch data events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch data plane operations on metrics GetMetricData, GetMetricWidgetImage, PutMetricData, GetMetricStatistics, and ListMetrics APIs.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

By default, CloudTrail doesn't log data events. The CloudTrail **Event history** doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

You can log data events for the CloudWatch resource types by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see Logging data events with the AWS Management Console and Logging data events with the AWS Command Line Interface in the *AWS CloudTrail User Guide*.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify any of the metric APIs, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the **GetMetricData**, **GetMetricWidgetImage**, **PutMetricData**, **GetMetricStatistics**, and **ListMetrics** APIs using CloudTrail helps you enable operational and risk auditing, governance, and compliance of your AWS account.

Note

When you view the **GetMetricData** events in CloudTrail, you might see more calls than the calls that you initiated. This is because CloudWatch logs events to CloudTrail for **GetMetricData** actions that are initiated by internal components. For example, you'll see **GetMetricData** calls initiated by CloudWatch dashboards to refresh widget data, and **GetMetricData** calls initiated by a monitoring account to retrieve data from a source account, in cross-account observability. These internally-initiated calls don't incur CloudWatch charges, but they do count toward the number of events logged in CloudTrail, and CloudTrail charges according to the number of events logged.

The following is an example of a CloudTrail event for a **GetMetricData** operation.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AIDA2NYTR2EPCTNY7AF3L",
        "arn": "arn:aws:iam::111122223333:user/admin",
        "accountId": "111122223333",
        "accessKeyId": "EXAMPLE1234567890",
        "userName": "admin"
    },
    "eventTime": "2024-05-08T16:20:34Z",
    "eventSource": "monitoring.amazonaws.com",
    "eventName": "GetMetricData",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "99.45.3.7",
    "userAgent": "aws-cli/2.13.23 Python/3.11.5 Darwin/23.4.0 exe/x86_64 prompt/off
 command/cloudwatch.get-metric-data",
    "requestParameters": {
        "metricDataQueries": [{
                "id": "e1",
                "expression": "m1 / m2",
                "label": "ErrorRate"
            },
            {
                "id": "m1",
                "metricStat": {
                    "metric": {
```

```
                        "namespace": "CWAgent",
                        "metricName": "disk_used_percent",
                        "dimensions": [{
                            "name": "LoadBalancerName",

                        }]
                    },
                    "period": 300,
                    "stat": "Sum",
                    "unit": "Count"
                },
                "returnData": false
            },
            {
                "id": "m2",
                "metricStat": {
                    "metric": {
                        "namespace": "CWAgent",
                        "metricName": "disk_used_percent",
                        "dimensions": [{
                            "name": "LoadBalancerName",
                            "value": "EXAMPLE4623a5cb6a7384c5229"
                        }]
                    },
                    "period": 300,
                    "stat": "Sum"
                },
                "returnData": true
            }
        ],
        "startTime": "Apr 19, 2024, 4:00:00 AM",
        "endTime": "May 8, 2024, 4:30:00 AM"
    },
    "responseElements": null,
    "requestID": "EXAMPLE-57ac-47d5-938c-f5917c6799d5",
    "eventID": "EXAMPLE-211c-404b-b13d-36d93c8b4fbf",
    "readOnly": true,
    "resources": [{
        "type": "AWS::CloudWatch::Metric"
    }],
    "eventType": "AwsApiCall",
    "managementEvent": false,
    "recipientAccountId": "111122223333",
    "eventCategory": "Data",
```

```
    "tlsDetails": {
        "tlsVersion": "TLSv1.3",
        "cipherSuite": "TLS_AES_128_GCM_SHA256",
        "clientProvidedHostHeader": "monitoring.us-east-1.amazonaws.com"
    }
}
```

The following is an example of a CloudTrail event for a **PutMetricData** operation.

```
{
      "eventVersion": "1.11",
      "userIdentity": {
        "type": "AssumedRole",
        "principalId": "111122223333:example.amazon.com",
        "arn": "arn:aws:sts::111122223333:assumed-role/
cloudwatch.full.access/example.amazon.com",
        "accountId": "111122223333",

Query generation information in CloudTrail

CloudTrail logging for Query generator console events is also supported. Query generator is currently supported for CloudWatch Metric Insights and CloudWatch Logs Insights. In these CloudTrail events, the `eventSource` is `monitoring.amazonaws.com`.

The following example shows a CloudTrail log entry that demonstrates the **GenerateQuery** action in CloudWatch Metrics Insights.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
```

```
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111222333444:role/Administrator",
                "accountId": "123456789012",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2020-04-08T21:43:24Z",
                "mfaAuthenticated": "false"
            }
        }
    },

Amazon Q Developer operational investigations events in CloudTrail

Amazon Q Developer operational investigations supports logging the following actions as events in CloudTrail log files.

- CreateInvestigationGroup
- GetInvestigationGroup
- DeleteInvestigationGroup
- ListInvestigationGroup
- PutInvestigationGroupPolicy
- DeleteInvestigationGroupPolicy
- ListTagsForResource
- GetInvestigationGroupPolicy
- TagResource
- UntagResource
- UpdateInvestigationGroup

Example: Amazon Q Developer operational investigations log file entries

The following example shows a Amazon Q Developer operational investigations log entry that demonstrates the `CreateInvestigationGroup` action.

```
{
 "eventVersion": "1.09",
 "userIdentity": {
  "type": "AssumedRole",
  "principalId": "EX_PRINCIPAL_ID",
  "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
  "accountId": "123456789012",
  "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
  "sessionContext": {
```

```
    "sessionIssuer": {
     "type": "Role",
     "principalId": "EX_PRINCIPAL_ID",
     "arn": "arn:aws:iam::123456789012:role/role_name",
     "accountId": "123456789012",
     "userName": "SAMPLE_NAME"
    },
    "attributes": {
     "creationDate": "2024-10-30T18:42:05Z",
     "mfaAuthenticated": "false"
    }
   }
  },
  "eventTime": "2024-10-30T18:48:26Z",
  "eventSource": "aiops.amazonaws.com",

Network Flow Monitor in CloudTrail

Network Flow Monitor supports logging the following actions as events in CloudTrail log files.

- CreateMonitor
- CreateScope
- DeleteMonitor
- DeleteScope
- GetMonitor
- GetScope
- ListMonitors
- ListScopes
- ListTagsForResource
- TagResource
- UntagResource
- UpdateMonitor
- UpdateScope

Example: Network Flow Monitor log file entry

The following example shows a Network Flow Monitor CloudTrail log file entry that demonstrates the `CreateMonitor` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::000000000000:assumed-role/role_name",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",

```

Network Flow Monitor data plane events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch-NetworkFlowMonitor data plane operations.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

To enable logging of Network Flow Monitor data events in CloudTrail files, you'll need to enable the logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify a specific request to the CloudWatch-NetworkFlowMonitor data plane APIs, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the data plane APIs using CloudTrail can help you with operational and risk auditing, governance, and compliance of your AWS account.

The following are data plane APIs in Network Flow Monitor.

- GetQueryResultsMonitorTopContributors
- GetQueryResultsMonitorsTopContributors
- GetQueryResultsWorkloadInsightsTopContributors
- GetQueryResultsWorkloadInsightsTopContributorsData
- GetQueryStatusMonitorTopContributors
- GetQueryStatusMonitorsTopContributors
- GetQueryStatusWorkloadInsightsTopContributors
- GetQueryStatusWorkloadInsightsTopContributorsData
- StartQueryMonitorTopContributors
- StartQueryMonitorsTopContributors
- StartQueryWorkloadInsightsTopContributors
- StartQueryWorkloadInsightsTopContributorsData
- StopQueryMonitorTopContributors
- StopQueryMonitorsTopContributors
- StopQueryWorkloadInsightsTopContributors
- StopQueryWorkloadInsightsTopContributorsData

The following example shows a CloudTrail log entry that demonstrates the GetQueryResultsMonitorsTopContributors action.

```
{
  "eventVersion": "1.09",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "EX_PRINCIPAL_ID",
    "arn": "arn:aws:iam::000000000000:assumed-role/role_name",

Internet Monitor in CloudTrail

Internet Monitor supports logging the following actions as events in CloudTrail log files.

- CreateMonitor
- DeleteMonitor
- GetHealthEvent
- GetMonitor
- GetQueryResults
- GetQueryStatus
- ListHealthEvents
- ListInternetEvents
- ListMonitors
- ListTagsForResource
- StartQuery
- StopQuery
- TagResource

- UntagResource
- UpdateMonitor

Example: Internet Monitor log file entries

The following example shows a CloudTrail Internet Monitor log entry that demonstrates the `ListMonitors` action.

```
{
        "eventVersion": "1.08",
        "userIdentity": {
            "type": "AssumedRole",
            "principalId": "EX_PRINCIPAL_ID",
            "arn": "arn:aws:iam::000000000000:assumed-role/role_name",
            "accountId":"123456789012",
            "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
            "sessionContext": {
                "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::000000000000:role/Admin",
                "accountId":"123456789012",
                "userName": "SAMPLE_NAME"
                },
                "webIdFederationData": {},
                "attributes": {
                    "creationDate": "2022-10-11T17:25:41Z",
                    "mfaAuthenticated": "false"
                }
            }
        },
        "eventTime": "2022-10-11T17:30:18Z",
        "eventSource": "internetmonitor.amazonaws.com",
        "eventName": "ListMonitors",
        "awsRegion": "us-east-2",
        "sourceIPAddress": "192.0.2.0",
        "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
        "requestParameters": null,
        "responseElements": null,

```

CloudWatch Synthetics information in CloudTrail

CloudWatch Synthetics supports logging the following actions as events in CloudTrail log files:

- AssociateResource
- CreateCanary
- CreateGroup
- DeleteCanary
- DeleteGroup
- DescribeCanaries
- DescribeCanariesLastRun
- DescribeRuntimeVersions
- DisassociateResource
- GetCanary
- GetCanaryRuns
- GetGroup
- ListAssociatedGroups
- ListGroupResources
- ListGroups
- ListTagsForResource

- StartCanary
- StartCanaryDryRun
- StopCanary
- TagResource
- UntagResource
- UpdateCanary

Example: CloudWatch Synthetics log file entries

The following example shows a CloudTrail Synthetics log entry that demonstrates the `DescribeCanaries` action.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
        "accountId":"123456789012",
        "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111222333444:role/Administrator",
                "accountId":"123456789012",
                "userName": "SAMPLE_NAME"
            },
            "webIdFederationData": {},
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "2020-04-08T21:43:24Z"
            }
        }
    },

CloudWatch RUM information in CloudTrail

CloudWatch RUM supports logging the following actions as events in CloudTrail log files:

- BatchCreateRumMetricDefinitions
- BatchDeleteRumMetricDefinitions
- BatchGetRumMetricDefinitions
- CreateAppMonitor
- DeleteAppMonitor
- DeleteResourcePolicy
- DeleteRumMetricsDestination
- GetAppMonitor

- GetAppMonitorData
- GetResourcePolicy
- ListAppMonitors
- ListRumMetricsDestinations
- ListTagsForResource
- PutResourcePolicy
- PutRumMetricsDestination
- TagResource
- UntagResource
- UpdateAppMonitor
- UpdateRumMetricDefinition

Example: CloudWatch RUM log file entries

This section contains example CloudTrail entries for some CloudWatch RUM APIs.

The following example shows a CloudTrail log entry that demonstrates the CreateAppMonitor action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EXAMPLE_PRINCIPAL_ID",
        "arn": "arn:aws:sts::777777777777:assumed-role/EXAMPLE",
        "accountId": "777777777777",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EXAMPLE_PRINCIPAL_ID",
                "arn": "arn:aws:iam::777777777777:role/EXAMPLE",
                "accountId": "777777777777",
                "userName": "USERNAME_EXAMPLE"
            },
            "attributes": {
                "creationDate": "2024-07-23T16:48:47Z",
                "mfaAuthenticated": "false"
```

```
            }
        }
    },
    "eventTime": "2024-07-23T18:02:57Z",
    "eventSource": "rum.amazonaws.com",

CloudWatch RUM data plane events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch RUM data plane operation PutRumEvents.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

To enable logging of the **PutRumEvents** data events in CloudTrail files, you'll need to enable the logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify a specific request to the CloudWatch RUM **PutRumEvents** API, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the **PutRumEvents** API using CloudTrail helps you enable operational and risk auditing, governance, and compliance of your AWS account.

The following example shows a CloudTrail log entry that demonstrates the PutRumEvents action.

```
{
 "Records": [
     {
         "eventVersion": "1.09",

Network Synthetic Monitor information in CloudTrail

Network Synthetic Monitor supports logging the following actions as events in CloudTrail log files:

- CreateMonitor
- CreateProbe
- DeleteMonitor
- DeleteProbe
- GetMonitor
- GetProbe
- ListMonitors
- ListTagsForResource
- TagResource
- UntagResource
- UpdateMonitor
- UpdateProbe

Example: Network Synthetic Monitor log file entries

The following example shows a Network Synthetic Monitor CloudTrail log entry that demonstrates the `CreateMonitor` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",

    "managementEvent": true,
    "recipientAccountId": "111122223333",
    "eventCategory": "Management"
}
```

CloudWatch Observability Access Manager information in CloudTrail

CloudWatch Observability Access Manager supports logging the following actions as events in CloudTrail log files:

- CreateLink

- CreateSink
- DeleteLink
- DeleteSink
- GetLink
- GetSink
- GetSinkPolicy
- ListAttachedLinks
- ListLinks
- ListSinks
- ListTagsForResource
- PutSinkPolicy
- TagResource
- UntagResource
- UpdateLink

Example: CloudWatch Observability Access Manager log file entries

The following example shows a CloudWatch Observability Access Manager CloudTrail log entry that demonstrates the `CreateSink` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",

}
```

CloudWatch Observability Admin information in CloudTrail

CloudWatch Observability Admin supports logging the following actions as events in CloudTrail log files:

- GetTelemetryEvaluationStatus
- GetTelemetryEvaluationStatusForOrganization
- ListResourceTelemetry
- ListResourceTelemetryForOrganization
- StartTelemetryEvaluation
- StartTelemetryEvaluationForOrganization

- StopTelemetryEvaluation
- StopTelemetryEvaluationForOrganization

Example: CloudWatch Observability Admin log file entries

The following example shows a CloudWatch Observability Admin CloudTrail log entry that demonstrates the `StartTelemetryEvaluation` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::111122223333:assumed-role/role_name",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2024-11-03T15:43:27Z",
                "mfaAuthenticated": "false"
            }
        }
    },
    "eventTime": "2024-11-03T15:58:11Z",
    "eventSource": "observabilityadmin.amazonaws.com",
    "eventName": "StartTelemetryEvaluation",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
    "requestParameters": {},
    "responseElements": null,

    "readOnly": false,
    "eventType": "AwsApiCall",
```

```
    "managementEvent": true,
    "recipientAccountId": "111122223333",
    "eventCategory": "Management"
}
```

CloudWatch Application Signals information in CloudTrail

CloudWatch Application Signals supports logging the following actions as events in CloudTrail log files:

- BatchGetServiceLevelObjectiveBudgetReport
- BatchUpdateExclusionWindows
- CreateServiceLevelObjective
- DeleteServiceLevelObjective
- GetService
- GetServiceLevelObjective
- ListServiceDependencies
- ListServiceDependents
- ListServiceLevelObjectives
- ListServiceOperations
- ListServices
- ListTagsForResource
- StartDiscovery
- TagResource
- UntagResource
- UpdateServiceLevelObjective

Example: CloudWatch Application Signals log file entries

The following example shows a CloudWatch Application Signals CloudTrail log entry that demonstrates the `CreateServiceLevelObjective` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
```

```
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::111122223333:assumed-role/role_name",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2024-11-03T15:43:27Z",
                "mfaAuthenticated": "false"
            }
        }
    },
    "eventTime": "2024-11-03T15:58:11Z",
    "eventSource": "applicationsignals.amazonaws.com",
    "eventName": "CreateServiceLevelObjective",

    "readOnly": false,
    "eventType": "AwsApiCall",
    "managementEvent": true,
    "recipientAccountId": "111122223333",
    "eventCategory": "Management"
}
```

CloudWatch Application Insights information in CloudTrail

CloudWatch Application Insights supports logging the following actions as events in CloudTrail log files:

- AddWorkload
- CreateApplication
- CreateComponent
- CreateLogPattern
- DeleteApplication
- DeleteComponent
- DeleteLogPattern
- DescribeApplication
- DescribeComponent
- DescribeComponentConfiguration
- DescribeComponentConfigurationRecommendation
- DescribeLogPattern
- DescribeObservation
- DescribeProblem
- DescribeProblemObservations
- DescribeWorkload
- ListApplications
- ListComponents
- ListConfigurationHistory
- ListLogPatterns
- ListLogPatternSets
- ListProblems
- ListTagsForResource
- ListWorkloads
- RemoveWorkload
- TagResource

- UntagResource
- UpdateApplication
- UpdateComponent
- UpdateComponentConfiguration
- UpdateLogPattern
- UpdateProblem
- UpdateWorkload

Example: CloudWatch Application Insights log file entries

The following example shows a CloudWatch Application Insights CloudTrail log entry that demonstrates the `CreateApplication` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {

Tagging your Amazon CloudWatch resources

A *tag* is a custom attribute label that you or AWS assigns to an AWS resource.

Tags help you do the following:

- Identify and organize your AWS resources. Many AWS services support tagging. You can assign the same tag to resources from different services to indicate the resources are related. For example, you can assign the tag that you assigned to a CloudWatch rule to an EC2 instance.

Tags have two parts:

- A *tag key* (for example, `CostCenter`, `Environment`, or `Project`). Tag keys are case sensitive.
- An optional field known as a *tag value* (for example, `111122223333` or `Production`). Omitting the tag value is the same as using an empty string. Like tag keys, tag values are case sensitive.

The following sections provide more information about tags for CloudWatch.

Supported resources in CloudWatch

The following resources in CloudWatch support tagging:

- Alarms – You can tag alarms using the tag-resource AWS CLI command and the TagResource API. You can also view and manage your alarm tags using the *Alarms* details page in the CloudWatch console.
- Canaries – You can tag canaries using the CloudWatch console. For more information, see Creating a canary.
- Contributor Insights rules – You can tag Contributor Insights rules when you create them by using the put-insight-rule AWS CLI command and the PutInsightRule API. You can add tags to existing rules by using the tag-resource AWS CLI command and the TagResource API.
- Metric streams – You can tag metric streams when you create them by using the put-metric-stream AWS CLI command and the PutMetricStream API. You can add tags to existing metric streams by using the tag-resource AWS CLI command and the TagResource API.

For information about adding and managing tags, see Managing tags.

Managing tags

Tags consist of the `Key` and `Value` properties on a resource. You can use the CloudWatch console, the AWS CLI, or the CloudWatch API to add, edit, or delete the values for these properties. For information about working with tags, see the following:

- TagResource, UntagResource, and ListTagsForResource in the *Amazon CloudWatch API Reference*
- tag-resource, untag-resource, and list-tags-for-resource in the *Amazon CloudWatch CLI Reference*
- Working with Tag Editor in the *Resource Groups User Guide*

Tag naming and usage conventions

The following basic naming and usage conventions apply to using tags with CloudWatch resources:

- Each resource can have a maximum of 50 tags.
- For each resource, each tag key must be unique, and each tag key can have only one value.
- The maximum tag key length is 128 Unicode characters in UTF-8.
- The maximum tag value length is 256 Unicode characters in UTF-8.
- Allowed characters are letters, numbers, spaces representable in UTF-8, and the following characters: ***. : + = @ _ / -*** (hyphen).
- Tag keys and values are case sensitive. As a best practice, decide on a strategy for capitalizing tags and consistently implement that strategy across all resource types. For example, decide whether to use `Costcenter`, `costcenter`, or `CostCenter` and use the same convention for all tags. Avoid using similar tags with inconsistent case treatment.
- The `aws:` prefix is prohibited for tags because it's reserved for AWS use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix don't count against your tags per resource limit.

Grafana integration

You can use Grafana version 6.5.0 and later to contextually advance through the CloudWatch console and query a dynamic list of metrics by using wildcards. This can help you monitor metrics for AWS resources, such as Amazon Elastic Compute Cloud instances or containers. When new instances are created as part of an Auto Scaling event, they appear in the graph automatically. You don't need to track the new instance IDs. Prebuilt dashboards help simplify the getting started experience for monitoring Amazon EC2, Amazon Elastic Block Store, and AWS Lambda resources.

You can use Grafana version 7.0 and later to perform CloudWatch Logs Insights queries on log groups in CloudWatch Logs. You can visualize your query results in bar, line, and stacked graphs and in a table format. For more information about CloudWatch Logs Insights, see Analyzing Log Data with CloudWatch Logs Insights.

For more information about how to get started, see Using AWS CloudWatch in Grafana in the Grafana Labs documentation.

CloudWatch service quotas

Amazon CloudWatch provides monitoring and observability for your AWS resources and applications. To ensure optimal performance and prevent abuse, CloudWatch imposes service quotas on various aspects of its functionality. This chapter outlines the key quotas for CloudWatch services, including metrics, alarms, API requests, and notifications. Understanding these quotas is crucial for effectively planning and managing your CloudWatch usage.

> **Note**
>
> For some AWS services including CloudWatch, you can use the CloudWatch usage metrics to visualize your current service usage on CloudWatch graphs and dashboards. You can use a CloudWatch metric math function to display the service quotas for those resources on your graphs. You can also configure alarms that alert you when your usage approaches a service quota. For more information, see Visualizing your service quotas and setting alarms.

- Managing your CloudWatch service quotas

CloudWatch

This section details the service quotas specifically for core CloudWatch functionality. These quotas cover aspects such as metrics, alarms, API requests, and dashboards. Familiarizing yourself with

these limits helps you optimize your CloudWatch configuration and avoid potential throttling or service disruptions.

Name	Default	Adjustable	Description
Canary limit	us-east-1: 300 ap-northeast-1: 300 Each of the other supported Regions: 500	Yes	The maximum number of canaries per account per region.
Minimum frequency	Each supported Region: 60,000 Milliseconds	No	The minimum time, in milliseconds, between runs of the same canary.
Number of Contributor Insights rules	Each supported Region: 100	Yes	The maximum number of Contributor Insights rules you can have in this account.
Number of Metrics Insights alarms	Each supported Region: 200	No	The maximum number of Metrics Insights alarms that you can have in this account in the current region.
Rate of ANOMALY_DETECTION_BAND usage in GetMetricData	Each supported Region: 1,000	No	The maximum number of times the ANOMALY_DETECTION_BAND function can be used in all GetMetricData requests, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of DB_PERF_INSIGHTS usage in GetMetricData	Each supported Region: 4	No	The maximum number of times the DB_PERF_INSIGHTS function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of DeleteAlarms requests	Each supported Region: 3 per second	No	The maximum number of DeleteAlarms requests that you can make, per second, in this account in the current region.
Rate of DeleteDashboards requests	Each supported Region: 10 per second	Yes	The maximum number of DeleteDashboards requests that you can make, per second, in this account in the current region.
Rate of DeleteInsightRules requests	Each supported Region: 5 per second	No	The maximum number of DeleteInsightRules requests you can make per second in this account.
Rate of DeleteMetricStream requests	Each supported Region: 10 per second	Yes	The maximum number of DeleteMetricStream requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of DescribeAlarmContributors requests	Each supported Region: 9 per second	Yes	The maximum number of DescribeAlarmContributors requests that you can make, per second, in this account in the current region.
Rate of DescribeAlarmHistory requests	Each supported Region: 20 per second	No	The maximum number of DescribeAlarmHistory requests that you can make, per second, in this account in the current region.
Rate of DescribeAlarms requests	Each supported Region: 9 per second	Yes	The maximum number of DescribeAlarms requests that you can make, per second, in this account in the current region.
Rate of DescribeAlarmsForMetric requests	Each supported Region: 9 per second	No	The maximum number of DescribeAlarmsForMetric requests that you can make, per second, in this account in the current region.
Rate of DescribeInsightRules requests	Each supported Region: 20 per second	No	The maximum number of DescribeInsightRules requests you can make per second in this account.

Name	Default	Adjustable	Description
Rate of DisableAlarmActions requests	Each supported Region: 3 per second	No	The maximum number of DisableAlarmActions requests that you can make, per second, in this account in the current region.
Rate of DisableInsightRules requests	Each supported Region: 1 per second	No	The maximum number of DisableInsightRules requests you can make per second in this account.
Rate of EnableAlarmActions requests	Each supported Region: 3 per second	No	The maximum number of EnableAlarmActions requests that you can make, per second, in this account in the current region.
Rate of EnableInsightRules requests	Each supported Region: 1 per second	No	The maximum number of EnableInsightRules requests you can make per second in this account.
Rate of GetDashboard requests	Each supported Region: 10 per second	Yes	The maximum number of GetDashboard requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of GetInsightRuleReport requests	Each supported Region: 20 per second	Yes	The maximum number of GetInsightRuleReport requests you can make, per second in this account.
Rate of GetMetricData datapoints for metrics older than three hours	Each supported Region: 396,000	No	The maximum number of GetMetricData datapoints that you can fetch, per second, for a request with a StartTime of more than three hours in this account in the current region.
Rate of GetMetricData datapoints for the last three hours of metrics	Each supported Region: 180,000	No	The maximum number of GetMetricData datapoints that you can fetch, per second, for a request with a StartTime of less than or equal to three hours in this account in the current region.
Rate of GetMetricData datapoints using Metrics Insights	Each supported Region: 4,300,000	No	The maximum number of GetMetricData datapoints that you can fetch using Metrics Insights, per second, for a request with a StartTime of less than or equal to three hours in this account in the current region.

Name	Default	Adjustable	Description
Rate of GetMetricData requests	Each supported Region: 50 per second	Yes	The maximum number of GetMetricData requests that you can make, per second, in this account in the current region.
Rate of GetMetricStatistics requests	Each supported Region: 400 per second	Yes	The maximum number of GetMetricStatistics requests that you can make, per second, in this account in the current region.
Rate of GetMetricStream requests	Each supported Region: 10 per second	Yes	The maximum number of GetMetricStream requests that you can make, per second, in this account in the current region.
Rate of GetMetricWidgetImage requests	Each supported Region: 20 per second	Yes	The maximum number of GetMetricWidgetImage requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of INSIGHT_RULE_METRIC usage in GetMetricData	Each supported Region: 20	No	The maximum number of times the INSIGHT_RULE_METRIC function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of LAMBDA usage in GetMetricData	Each supported Region: 5	No	The maximum number of times the LAMBDA function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of ListDashboards requests	Each supported Region: 10 per second	Yes	The maximum number of ListDashboards requests that you can make, per second, in this account in the current region.
Rate of ListMetricStreams requests	Each supported Region: 10 per second	Yes	The maximum number of ListMetricStreams requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of ListMetrics requests	Each supported Region: 25 per second	Yes	The maximum number of ListMetrics requests that you can make, per second, in this account in the current region.
Rate of ListTagsForResource requests	Each supported Region: 10 per second	No	The maximum number of ListTagsForResource requests that you can make, per second, in this account in the current region.
Rate of Metrics Insights usage in GetMetricData	Each supported Region: 10	No	The maximum number of times Metrics Insights can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of PutCompositeAlarm requests	Each supported Region: 3 per second	Yes	The maximum number of PutCompositeAlarm requests that you can make, per second, in this account in the current region.
Rate of PutDashboard requests	Each supported Region: 10 per second	Yes	The maximum number of PutDashboard requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of PutInsightRule requests	Each supported Region: 5 per second	No	The maximum number of PutInsightRule requests you can make, per second in this account.
Rate of PutMetricAlarm requests	Each supported Region: 3 per second	Yes	The maximum number of PutMetricAlarm requests that you can make, per second, in this account in the current region.
Rate of PutMetricData requests	Each supported Region: 500 per second	Yes	The maximum number of PutMetricData requests that you can make, per second, in this account in the current region.
Rate of PutMetricStream requests	Each supported Region: 10 per second	Yes	The maximum number of PutMetricStream requests that you can make, per second, in this account in the current region.
Rate of SEARCH usage in GetMetricData	Each supported Region: 50	No	The maximum number of times the SEARCH function can be used in all GetMetricData requests, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of SERVICE_QUOTA usage in GetMetricData	Each supported Region: 1,000	No	The maximum number of times the SERVICE_QUOTA function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of SetAlarmState requests	Each supported Region: 3 per second	No	The maximum number of SetAlarmState requests that you can make, per second, in this account in the current region.
Rate of StartMetricStreams requests	Each supported Region: 10 per second	Yes	The maximum number of StartMetricStreams requests that you can make, per second, in this account in the current region.
Rate of StopMetricStreams requests	Each supported Region: 10 per second	Yes	The maximum number of StopMetricStreams requests that you can make, per second, in this account in the current region.
Rate of TagResource requests	Each supported Region: 20 per second	No	The maximum number of TagResource requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of UntagResource requests	Each supported Region: 20 per second	No	The maximum number of UntagResource requests that you can make, per second, in this account in the current region.

CloudWatch investigations (Amazon AI Operations)

CloudWatch investigations (Amazon AI Operations) enables intelligent problem detection and root cause analysis. This section outlines the quotas related to concurrent investigations, investigation groups, and AI-assisted analyses.

Name	Default	Adjustable	Description
Concurrent active investigations	Each supported Region: 2	No	The maximum number of concurrent investigations with active AI analysis per account per region.
Investigation groups	Each supported Region: 1	No	The maximum number of investigation groups that can be created per account in a region.
Monthly investigations	Each supported Region: 150	No	The maximum number of AI-assisted investigations per month in this account in the current region.

CloudWatch Application Insights

CloudWatch Application Insights helps you monitor your applications and troubleshoot issues quickly. This section presents the quotas for CloudWatch Application Insights, including limits on API requests, applications, log streams, and metrics. Knowing these quotas allows you to effectively plan your application monitoring setup.

Resource	Default quota	Adjustable
API requests	All API actions are throttled to 5 TPS	No
Resource Group applications	100 per account	No
Account applications	1 per account	No
Log Streams	5 per resource	No
Observations per problem	20 per dashboard 40 per DescribeProblemObservations action	No
Metrics	60 per resource	No

CloudWatch Application Signals

CloudWatch Application Signals provides deep insights into your application's performance and dependencies. This section covers the quotas for Application Signals, including API request limits and service-level objective (SLO) constraints. Understanding these quotas is crucial for implementing effective application performance monitoring.

Name	Default	Adjustable	Description
Number of SLOs per Region	Each supported Region: 250	Yes	The maximum number of SLOs that you can have

Name	Default	Adjustable	Description
			in this account in the current region.
Number of SLOs per Service	Each supported Region: 100	Yes	The maximum number of SLOs that you can have per service in the current region.
Rate of BatchGetServiceLevelObjectiveBudgetReport requests	Each supported Region: 10 per second	Yes	The maximum number of BatchGetServiceLevelObjectiveBudgetReport requests you can make per second in this Region.
Rate of BatchUpdateExclusionWindows requests	Each supported Region: 5 per second	Yes	The maximum number of BatchUpdateExclusionWindows requests you can make per second in this Region.
Rate of CreateServiceLevelObjective requests	Each supported Region: 5 per second	Yes	The maximum number of CreateServiceLevelObjective requests you can make per second in this Region.
Rate of DeleteGroupingConfiguration requests	Each supported Region: 10 per second	Yes	The maximum number of DeleteGroupingConfiguration requests you can make per second in this Region.

Name	Default	Adjustable	Description
Rate of DeleteServiceLevelObjective requests	Each supported Region: 5 per second	Yes	The maximum number of DeleteServiceLevelObjective requests you can make per second in this Region.
Rate of GetService requests	Each supported Region: 10 per second	Yes	The maximum number of GetService requests you can make per second in this Region.
Rate of GetServiceLevelObjective requests	Each supported Region: 5 per second	Yes	The maximum number of GetServiceLevelObjective requests you can make per second in this Region.
Rate of ListAuditFindings requests	Each supported Region: 1 per second	Yes	The maximum number of ListAuditFindings requests you can make per second in this Region.
Rate of ListGroupingAttributeDefinitions requests	Each supported Region: 10 per second	Yes	The maximum number of ListGroupingAttributeDefinitions requests you can make per second in this Region.
Rate of ListServiceDependencies requests	Each supported Region: 10 per second	Yes	The maximum number of ListServiceDependencies requests you can make per second in this Region.

Name	Default	Adjustable	Description
Rate of ListServiceDependents requests	Each supported Region: 10 per second	Yes	The maximum number of ListServiceDependents requests you can make per second in this Region.
Rate of ListServiceLevelObjectiveExclusionWindows requests	Each supported Region: 5 per second	Yes	The maximum number of ListServiceLevelObjectiveExclusionWindows requests you can make per second in this Region.
Rate of ListServiceLevelObjectives requests	Each supported Region: 5 per second	Yes	The maximum number of ListServiceLevelObjectives requests you can make per second in this Region.
Rate of ListServiceOperations requests	Each supported Region: 10 per second	Yes	The maximum number of ListServiceOperations requests you can make per second in this Region.
Rate of ListServiceStates requests	Each supported Region: 5 per second	Yes	The maximum number of ListServiceStates requests you can make per second in this Region.
Rate of ListServices requests	Each supported Region: 10 per second	Yes	The maximum number of ListServices requests you can make per second in this Region.

Name	Default	Adjustable	Description
Rate of ListTagsForResource requests	Each supported Region: 5 per second	Yes	The maximum number of ListTagsForResource requests you can make per second in this Region.
Rate of PutGroupingConfiguration requests	Each supported Region: 10 per second	Yes	The maximum number of PutGroupingConfiguration requests you can make per second in this Region.
Rate of StartDiscovery requests	Each supported Region: 5 per second	Yes	The maximum number of StartDiscovery requests you can make per second in this Region.
Rate of TagResource requests	Each supported Region: 5 per second	Yes	The maximum number of TagResource requests you can make per second in this Region.
Rate of UntagResource requests	Each supported Region: 5 per second	Yes	The maximum number of UntagResource requests you can make per second in this Region.
Rate of UpdateServiceLevelObjective requests	Each supported Region: 5 per second	Yes	The maximum number of UpdateServiceLevelObjective requests you can make per second in this Region.

Internet Monitor

Internet Monitor, a feature of CloudWatch Network Monitoring, helps you understand how internet issues impact your application's performance. This section provides the quotas specific to Internet Monitor, to help you to plan an effective internet performance monitoring strategy.

Name	Default	Adjuse	Description
Days that health events are retained	Each supported Region: 400	No	The number of days that AWS keeps information about a resolved Internet Monitor health event.
Monitors per account per AWS Region	Each supported Region: 50	No	The maximum number of monitors in an account in one AWS Region.
Resources per monitor	Each supported Region: 50	No	The maximum number of resources that a monitor can have.

Network Flow Monitor

Network Flow Monitor, a feature of CloudWatch Network Monitoring, provides near real-time visibility into network performance, such as packet loss and latency, for traffic between Amazon EC2 instances, as well as traffic toward certain other AWS services. It also helps you to determine if AWS issues are causing network performance degradation for your application. This section provides the quotas for Network Flow Monitor, including limits on monitored flows, data retention, and API requests. Understanding these quotas can help you to plan an effective network flow monitoring strategy.

Resource	Default quota	Adjustable?
Scopes per account per AWS Region	1	No

Resource	Default quota	Adjustable?
Monitors per account per AWS Region	20	Yes
Local resources per monitor	25	No
Remote resources per monitor	25	No

Network Synthetic Monitor

Network Synthetic Monitor, a feature of CloudWatch Network Monitoring, enables you to proactively monitor your network endpoints and API operations using configurable tests. This section details the quotas for Network Synthetic Monitor, including limits on synthetic monitors, test frequency, and script execution. These quotas are important for planning your network testing strategy and maintaining reliable endpoint monitoring.

Name	Default	Adjuse	Description
Number of monitors per account per AWS region	Each supported Region: 100	Yes	The maximum number of monitors in an account in one AWS Region.
Number of probes per monitor	Each supported Region: 24	Yes	The maximum number of probes that a monitor can have.
Number of probes per subnet for each monitor	Each supported Region: 4	Yes	The maximum number of probes that a subnet in a monitor can have.

CloudWatch Observability Access Manager

CloudWatch Observability Access Manager allows you to securely share CloudWatch resources across accounts. This section details the quotas for Observability Access Manager, including limits on API requests, source account links, and sinks. Understanding these quotas is essential for implementing cross-account observability effectively.

Name	Default	Adjuse	Description
Links per sink	Each supported Region: 100,000	No	Maximum number of links that can be attached to a sink
Number of links	Each supported Region: 5	No	Maximum number of links in your account
Number of sinks	Each supported Region: 1	No	Maximum number of sinks in your account
Rate of CreateLink requests	Each supported Region: 10 per second	No	Maximum number of CreateLink requests you can make per second, in this account in the current region
Rate of CreateSink requests	Each supported Region: 10 per second	No	Maximum number of CreateSink requests you can make per second, in this account in the current region
Rate of DeleteLink requests	Each supported Region: 10 per second	No	Maximum number of DeleteLink requests you can make per second, in this account in the current region

Name	Default	Adjustable	Description
Rate of DeleteSink requests	Each supported Region: 10 per second	No	Maximum number of DeleteSink requests you can make per second, in this account in the current region
Rate of GetLink requests	Each supported Region: 10 per second	No	Maximum number of GetLink requests you can make per second, in this account in the current region
Rate of GetSink requests	Each supported Region: 10 per second	No	Maximum number of GetSink requests you can make per second, in this account in the current region
Rate of GetSinkPolicy requests	Each supported Region: 10 per second	No	Maximum number of GetSinkPolicy requests you can make per second, in this account in the current region
Rate of ListAttachedLinks requests	Each supported Region: 10 per second	No	Maximum number of ListAttachedLinks requests you can make per second, in this account in the current region

Name	Default	Adjustable	Description
Rate of ListLinks requests	Each supported Region: 10 per second	No	Maximum number of ListLinks requests you can make per second, in this account in the current region
Rate of ListSinks requests	Each supported Region: 10 per second	No	Maximum number of ListSinks requests you can make per second, in this account in the current region
Rate of ListTagsForResource requests	Each supported Region: 10 per second	No	Maximum number of ListTagsForResource requests you can make per second, in this account in the current region
Rate of PutSinkPolicy requests	Each supported Region: 1 per second	No	Maximum number of PutSinkPolicy requests you can make per second, in this account in the current region
Rate of TagResource requests	Each supported Region: 10 per second	No	Maximum number of TagResource requests you can make per second, in this account in the current region

Name	Default	Adjustable	Description
Rate of UntagResource requests	Each supported Region: 10 per second	No	Maximum number of UntagResource requests you can make per second, in this account in the current region
Rate of UpdateLink requests	Each supported Region: 10 per second	No	Maximum number of UpdateLink requests you can make per second, in this account in the current region

CloudWatch RUM

CloudWatch RUM (Real-User Monitoring) helps you collect and analyze performance data from real user interactions with your web applications. This section presents the quotas for CloudWatch RUM, allowing you to plan your real-user monitoring strategy within the service limits.

Name	Default	Adjustable	Description
RUM AppMonitors	Each supported Region: 20	Yes	The maximum number of RUM AppMonitors that you can have in this AWS account.
RUM Events per second per AWS Account	Each supported Region: 50	Yes	The maximum number of RUM Events per second that RUM will ingest for this AWS account.

Managing your CloudWatch service quotas

Effective management of CloudWatch service quotas is crucial for maintaining optimal performance and avoiding service disruptions. This section provides guidance on viewing your current quota usage, requesting quota increases when necessary, and best practices for working within CloudWatch service limits.

CloudWatch quotas are integrated with Service Quotas, an AWS service that enables you to view and manage your quotas from a central location. For more information, see What Is Service Quotas? in the *Service Quotas User Guide*.

AWS Management Console

To view CloudWatch service quotas using the console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.
2. In the navigation pane, choose **AWS services**.
3. From the **AWS services** list, search for and select the CloudWatch service whose quotas you want to view.

   In the **Service quotas** list, you can see the service quota name, applied value (if it is available), AWS default quota, and whether the quota value is adjustable.
4. To view additional information about a service quota, such as the description, choose the quota name.
5. (Optional) To request a quota increase, select the quota that you want to increase, select **Request quota increase**, enter or select the required information, and select **Request**.

To work more with service quotas using the console see the Service Quotas User Guide. To learn more about quota increases, see Requesting a quota increase in the *Service Quotas User Guide*.

AWS CLI

To view CloudWatch service quotas using the AWS CLI

1. Run the following command to view the default CloudWatch quotas.

```
aws service-quotas list-aws-default-service-quotas \
    --query 'Quotas[*].
{Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}' \
```

```
    --service-code ServiceCode
    --output table
```

> **Note**
>
> The following list contains the CloudWatch **ServiceCode** values:
>
> - To see the CloudWatch quotas, use `--service-code monitoring`.
> - To see the Amazon AI Operations quotas, use `--service-code aiops`.
> - To see the CloudWatch Application Signals quotas, use `--service-code application-signals`.
> - To see the Amazon CloudWatch Internet Monitor quotas, use `--service-code internetmonitor`.
> - To see the CloudWatch Network Monitor quotas, use `--service-code networkmonitor`.
> - To see the CloudWatch Observability Access Manager quotas, use `--service-code oam`.
> - To see the CloudWatch RUM (Real-User Monitoring) quotas, use `--service-code rum`.

2. (Optional) Request a quota increase for a CloudWatch service:

   a. Identify the quota code for the quota you want to increase.

   ```
   aws service-quotas list-service-quotas --service-code ServiceCode
   ```

   b. Note the `QuotaCode` value for the item. For example if you wanted to increase your quota for the **Rate of PutCompositeAlarm requests** that are supported by CloudWatch for your account, you would record the **QuotaCode** `L-8742A250`.

   c. Type the following command using the identified `ServiceCode` and `QuotaCode` values and providing the numeric value for the desired new quota:

```
aws service-quotas request-service-quota-increase \
    --service-code ServiceCode \
    --quota-code QuotaCode \
    --desired-value new-quota-value
```

For more details about quota increases, see the `request-service-quota-increase` command in the AWS CLI Command Reference.

To work more with service quotas using the AWS CLI, see the Service Quotas AWS CLI Command Reference.

Document history

The following table describes important changes for each release of the *Amazon CloudWatch User Guide*, beginning in June 2018. To receive notifications about updates to this documentation, you can subscribe to an RSS feed.

Change	Description	Date
Updated CloudWatchApplicationSignalsReadOnlyAccess policy	CloudWatch updated the `CloudWatchApplicationSignalsReadOnlyAccess` policy to view how resources and services change in your account and view top observations for service anomalies in your account. For more information, see CloudWatchApplicationSignalsReadOnlyAccess.	September 29, 2025
Updated CloudWatchApplicationSignalsFullAccess policy	CloudWatch updated the `CloudWatchApplicationSignalsFullAccess` policy to view how resources and services change in your account and view top observations for service anomalies in your account. For more information, see CloudWatchApplicationSignalsFullAccess.	September 29, 2025
CloudWatch Application Signals added support for dynamic service grouping and filtering, last deploymen	You can group and filter services with Application Signals' dynamic grouping capabilities track deployment activities through Application	September 29, 2025

t tracking, and automated audit findings	Signals' automatic processing of CloudTrail events, and discover critical insights through Application Signals' automated audit findings. For more information, see Application Signals.	
Update to AIOPsAssistantPolicy managed policy	CloudWatch updated the **AIOpsAssistantPolicy** to allow CloudWatch investigations access to additional resources to assist in queries, troubleshooting, and topology mapping. For more information, see AIOpsAssistantPolicy.	September 24, 2025
New AWSObservabilityAdminLogsCentralizationServiceRolePolicy policy	CloudWatch added the **AWSObservabilityAdminLogsCentralizationServiceRolePolicy** that grants CloudWatch permission to use telemetry data from other AWS accounts that you specify to create CloudWatch log groups, log streams, and log events in your organization's monitoring account. The SLR only provides the assume role permission to allow the CloudWatch service to assume the role in the monitoring account. For more information, see AWSObservabilityAdminLogsCentralizationServiceRolePolicy.	September 17, 2025

CloudWatch added support for Cross-account cross-Region log centralization	CloudWatch added support for the **Cross-account cross-Region log centralization** that enables CloudWatch Logs to gather log data from AWS Organizations member accounts into a central account for analysis. For more information, see Monitor across accounts and Regions.	September 17, 2025
Collect EC2 instance store volume NVMe driver metrics	You can now use the CloudWatch agent to collect AWS NVMe driver metrics for instance store volumes attached to Nitro-based Amazon EC2 instances.	September 16, 2025
Removed AWS OpsWorks metrics and dimensions	AWS OpsWorks reached end-of-life and the service is deprecated.	August 20, 2025
New AWSObservabilityAdminTelemetryEnablementServiceRolePolicy policy	CloudWatch added the **AWSObservabilityAdminTelemetryEnablementServiceRolePolicy** that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for AWS resources based on telemetry rules. For more information, see AWSObservabilityAdminTelemetryEnablementServiceRolePolicy.	July 17, 2025

Gen AI observability	With CloudWatch, you can observe generative AI workloads, including Amazon Bedrock AgentCore agents, and gain insights into AI performance, health, and accuracy. For more information, see Generative AI observability.	July 16, 2025
AIOpsReadOnlyAccess policy updated	CloudWatch updated the **AIOpsReadOnlyAccess** policy to permit validation of investigation groups across accounts. For more informati on, see AIOpsReadOnlyAccess policy.	June 23, 2025
Updated AIOpsCons oleAdminPolicy policy	CloudWatch updated the AIOpsConsoleAdminPolicy policy to permit validation of investigation groups across accounts. For more informati on, see AIOpsConsoleAdminP olicy policy.	June 13, 2025
Updated AIOpsAssistantPolicy policy	CloudWatch updated the AIOpsAssistantPolicy policy to provide additional IAM permissions. For more information, see AIOpsCons oleAdminPolicy policy.	June 13, 2025

Update managed policy	CloudWatch updated the **AIOpsOperatorAccess** policy to permit validation of investigation groups across accounts. For more informati on, see AIOpsOperatorAccess.	June 13, 2025
AmazonCloudWatchRU MReadOnlyAccess updated	The `synthetics: describeCanaries` , `synthetics:describ eCanariesLastRun` , `cloudwatch:GetMetr icData` , `cloudwatc h:DescribeAlarms` , `logs:DescribeLogGr oups` , `xray:GetT raceSummaries` , and `rum:ListTagsForRes ources` permissions was added to the CloudWatc h RUM `AmazonClo udWatchRUMReadOnly Access` policy.	June 12, 2025
Added functionality	You can now monitor Amazon Aurora PostgreSQL Limitless Databases at the instance level from the Database Instance Dashboard. For more information, see Monitorin g Aurora Limitless databases with Database Insights.	May 22, 2025

Added functionality	You can now enable Application Signals for your applications on an existing Amazon EKS cluster using CloudWatch Observability add-on Auto monitor advanced configuration. For more information, see Enable Application Signals on an Amazon EKS cluster using the CloudWatch Observability add-on advanced configuration.	May 19, 2025
CloudWatch Network Monitoring releases multiple account support for Network Flow Monitor	Network Flow Monitor, a feature of CloudWatch Network Monitoring, now supports monitoring network performance metrics for network flows for resources in multiple accounts. For more information, see Initialize Network Flow Monitor for multi-account monitoring.	May 6, 2025
AmazonCloudWatchRUMReadOnlyAccess updated	The `rum:GetResourcePolicy` permission was added so that CloudWatch RUM can view the resource policy attached to the RUM application monitor.	April 28, 2025

Updated AIOpsAssistantPolicy policy	CloudWatch added permissions to the **AIOpsAssistantPolicy** policy, which Amazon Q Developer operational investigations uses to find information during investigations.	April 11, 2025
CloudWatch Synthetics deprecates five runtime metrics on October 1, 2025	CloudWatch Synthetics metrics `syn-nodejs-puppeteer-7.0` , `syn-nodejs-puppeteer-6.2` , `syn-nodejs-puppeteer-5.2` , `syn-python-selenium-3.0` , and `syn-python-selenium-2.1` will be deprecated on October 1, 2025.	April 4, 2025
Updated CloudWatchApplicationSignalsServiceRolePolicy policy	CloudWatch updated the policy to exclude time windows from impacting the SLO attainment rate, error budget, and burn rate metrics. CloudWatch can retrieve exclusion windows on behalf of you. For more information, see CloudWatchApplicationSignalsServiceRolePolicy.	March 13, 2025

Time window exclusions	SLOs adds support for time window exclusions which is a block of time with a defined start and end date. This time period is excluded from the SLO's performance metrics and you can schedule one-time or recurring time exclusions windows. For more information, see Service level objectives (SLOs).	March 13, 2025
New AIOpsReadOnlyAccess policy	CloudWatch added the **AIOpsReadOnlyAccess** policy, which grants read-only permissions for Amazon AI Operations and other related services.	December 3, 2024
New AIOpsOperatorAccess policy	CloudWatch added the **AIOpsOperatorAccess** policy, which grants users access to Amazon AI Operations actions, and to additiona l AWS actions that are necessary for accessing investigation events.	December 3, 2024

New AIOpsConsoleAdminPolicy policy	CloudWatch added the **AIOpsConsoleAdminPolicy** policy, which grants users full administrative access for managing Amazon Q investigations, including the management of trusted identity propagation, and the management of IAM Identity Center and organizational access.	December 3, 2024
New AIOpsAssistantPolicy policy	CloudWatch added the **AIOpsAssistantBasicAccess** policy, which you can assign to the Amazon AI Operations assistant to enable the assistant to have basic functionality.	December 3, 2024
Amazon Q Developer operational investigations feature in Preview	CloudWatch released a Preview of Amazon Q Developer operational investigations. This feature is a generative AI-powered assistant that can help you respond to incidents in your system. It uses generative AI to scan your system's telemetry and quickly surface suggestions that might be related to your issue, to help you troubleshoot operational issues faster.	December 3, 2024

CloudWatchFullAccessV2 and CloudWatchFullAccess policies updated	CloudWatch updated both **CloudWatchFullAccessV2** and **CloudWatchFullAccess**. Permissions for Amazon OpenSearch Service were added to to enable CloudWatch Logs integration with OpenSearch Service for some features.	December 1, 2024
Telemetry config feature generally available	CloudWatch added the telemetry config feature to discover and understand the state of telemetry configuration for your AWS resources.	November 26, 2024
New AWSServiceRoleForObservabilityAdmin service-linked role	CloudWatch added the new AWSServiceRoleForObservabilityAdmin service-linked role and AWSObservabilityAdminServiceRolePolicy policy.	November 26, 2024
CloudWatch supports exploring related telemetry	CloudWatch supports exploring related telemetry data across interconnected resources.	November 22, 2024

Updated CloudWatchSyntheticsFullAccess IAM policy	CloudWatch updated the **CloudWatchSyntheticsFullAccess** policy to grant CloudWatch Synthetics access to get AWS Lambda functions , and perform actions on logs available in CloudWatch Logs. Additionally, Lambda layer version actions apply to all CloudWatch Synthetics layer ARNs.	November 21, 2024
New CloudWatch Synthetics support for Node.js with the Playwright runtime	CloudWatch Synthetics adds support for Node.js canary scripts that use the Playwright runtime.	November 21, 2024
CloudWatchReadOnlyAccess policy updated	The scope of the policy was changed to include the `xray:List *`, `xray:StartTraceRetrieval` , and `xray:CancelTraceRetrieval` permissions. This change allows CloudWatch to access new X-Ray read APIs. For more infomration, see CloudWatchReadOnlyAccess.	November 21, 2024

CloudWatch Transaction Search is generally available	CloudWatch releases Transaction Search, a search and analytics experience. Transaction Search provides visibility into application transaction issues. Explore interactions between application components to establish a root cause. Understand your application transactions and their impact on customers. Search transactions using terms like customer name or order. For more information, see CloudWatch Transaction Search.	November 21, 2024
Application Signals supports Lambda functions	You can now enable Application Signals for Lambda functions.	November 21, 2024
OpenTelemetry	You can use OpenTelemetry to directly send traces to an OpenTelemetry Protocol (OTLP) endpoint, and get out-of-the box application performance monitoring experiences in CloudWatch Application Signals.	November 20, 2024
Application Signals collects runtime metrics	Application Signals now collects OpenTelemetry-compatible runtime metrics from your Java and Python applications.	November 19, 2024

Application Signals collects runtime metrics	Application Signals now collects OpenTelemetry-compatible runtime metrics from your Java and Python applications.	November 19, 2024
Internet traffic monitoring for VPCs in AWS Local Zones	Internet Monitor now supports internet traffic monitoring for VPCs deployed in AWS Local Zones	November 18, 2024
Application Signals support for Node.js applications is generally available	CloudWatch supports enabling Node.js applications for Application Signals.	November 15, 2024
New CloudWatchInternetMonitorReadOnlyAccess IAM policy	CloudWatch added a **CloudWatchInternetMonitorReadOnlyAccess** policy, to grant read-only access to actions and resources available in the CloudWatch console for Internet Monitor.	November 14, 2024
CloudWatch added observability solutions	CloudWatch observability solutions offer a catalog of readily available configurations to help you quickly implement monitoring for various AWS services and common workloads, such as Java Virtual Machines (JVM), Apache Kafka, Apache Tomcat, and NGINX.	November 13, 2024

CloudWatch added burn rate monitoring for Application Signals SLOs	CloudWatch added burn rate monitoring to Application Signals SLOs. A burn rate is a metric that indicates how fast the service is consuming the error budget, relative to the attainment goal of the SLO.	November 13, 2024
New Internet Monitor latency reduction suggestions through Route 53 routing updates	Amazon CloudWatch Internet Monitor now provides actionable suggestions to help you optimize your Route 53 IP-based routing configurations. Easily identify the optimal AWS Regions for routing your end user traffic, and then configure your Route 53 IP-based routing based on the recommend ations.	November 1, 2024
New CloudWatchInternet MonitorFullAccess IAM policy	CloudWatch added a **CloudWatchInternet MonitorFullAccess** policy, to grant full access to actions and resources available in the CloudWatch console for Internet Monitor.	October 23, 2024
End of support notice	End of support notice: On October 16, 2025, AWS will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.	October 17, 2024

End of support notice	End of support notice: On October 16, 2025, AWS will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.	October 17, 2024
New CloudWatchLambdaApplicationSignalsExecutionRolePolicy IAM policy	CloudWatch added a new policy named **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024
New CloudWatchLambdaApplicationSignalsExecutionRolePolicy IAM policy	CloudWatch added a new policy named **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024

CloudWatchSyntheticsFullAccess policy updated	Permissions were added to the **CloudWatchSyntheticsFullAccess** IAM policy. The `lambda:ListTags` , `lambda:TagResource` , and `lambda:UntagResource` permissions were added so that when you apply or change tags on a canary, you can choose to have Synthetics also apply those same tags or changes to the Lambda function that the canary uses.	October 11, 2024
Application Signals supports request-based SLOs	Application Signals adds support for request-based service level objects (SLOs). For more information, see Service level objectives (SLOs).	September 6, 2024
Internet Monitor refreshed dashboard and latency improvement suggestions	Amazon CloudWatch Internet Monitor has launched an updated console experience, including new features for visualizing configuration changes that can help you reduce latency for your application.	August 12, 2024
Application Signals previewing support for .NET applications	CloudWatch Application Signals has added support for .NET applications, with ADOT Instrumentation for .NET on supported platforms. This feature is in preview release.	August 5, 2024

New CloudWatch Application Insights service linked role permission added	Allows CloudWatch Application Insights to enable and disable termination protection on AWS CloudFormation stacks.	July 25, 2024
CloudWatch Metrics Insights support for natural language query generation is generally available.	CloudWatch Metrics Insights supports natural language query to generate and update queries. For more information, see Use natural language to generate and update CloudWatch Metric Insights queries.	June 10, 2024
CloudWatch Application Signals is generally available	CloudWatch Application Signals is now generally available. Use Application Signals to instrument your applications on AWS so that you can monitor current application health, create service level objectives (SLOs), and track long-term application performance against your business objectives. For more information, see Application Signals.	June 10, 2024
New CloudWatchApplicationSignalsReadOnlyAccess IAM policy	CloudWatch added a **CloudWatchApplicationSignalsReadOnlyAccess** policy to add read only actions and resources available in the CloudWatch console for Application Signals.	June 7, 2024

New CloudWatchApplicationSignalsFullAccess policy	CloudWatch added a **CloudWatchApplicationSignalsFullAccess** policy to add actions and resources available in the CloudWatch console for Application Signals.	June 7, 2024
CloudTrail now captures API activities related to CloudWatch data plane operations.	CloudTrail now logs events in CloudTrail for **GetMetricData** and **GetMetricWidgetImage** API activities.	June 6, 2024
CloudWatch Application Signals application map supports canary, RUM clients and AWS service dependency groupings.	The Application Signals preview release has added default groupings in the application map for canaries, RUM clients, and AWS service dependencies of the same type. This change reduces the number of icons in the application map default view to make it easier to view and navigate.	May 21, 2024

CloudWatchReadOnlyAccess policy updated	CloudWatch changed the scope of a permission in **CloudWatchReadOnlyAccess**. The scope of the policy added the `application-signals:BatchGet*` , `application-signals:Get*` , and `application-signals:List*` actions so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services. CloudWatch also added an `iam:GetRole` action so that users can check if Application Signals is set up.	May 17, 2024
CloudWatchFullAccessV2 policy updated	CloudWatch changed the scope of a permission in **CloudWatchFullAccessV2**. The scope of the policy added the `application-signals:*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services.	May 17, 2024
Lambda Insights supports AWS GovCloud (US-East) and AWS GovCloud (US-West)	CloudWatch Lambda Insights has added support for the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions.	April 29, 2024

CloudWatch cross-account observability supports resource filters	You can now create filters to specify which metric namespaces and log groups are shared from the source account to the monitoring account, when you create the link between the accounts.	April 26, 2024
CloudWatch Application Signals updates	The Application Signals preview release has added three features. Applicati on Signals now supports Python applications. It offers a simpler enablement process for applications on Amazon EKS architectures. And it includes new configurations that you can use to manage the cardinality of metrics that are collected.	April 26, 2024
CloudWatch Container Insights with enhanced observability for Amazon EKS can collect AWS Elastic Fabric Adapter (EFA) metrics	You can now use CloudWatc h Container Insights with enhanced observability for Amazon EKS collect AWS Elastic Fabric Adapter (EFA) metrics from Amazon EKS clusters.	April 23, 2024

Updated IAM policy	CloudWatch updated the **CloudWatchApplicationSignalsServiceRolePolicy** policy. The scoping of the `logs:StartQuery` and `logs:GetQueryResults` permissions in this policy was changed to add `arn:aws:logs:*:*:log-group:/aws/appsignals/*:*` and `"arn:aws:logs:*:*:log-group:/aws/application-signals/data:*"` to enable Application Signals on more architecures. This policy is attached to the **AWSServiceRoleForCloudWatchApplicationSignals** service-linked role.	April 18, 2024
Internet Monitor provides a global internet weather map to authenticated AWS customers	Amazon CloudWatch Internet Monitor now displays a global internet weather map that is available in the console to all authenticated AWS customers. To view the map, in the Amazon CloudWatch console, navigate to Internet Monitor.	April 16, 2024
CloudWatch Container Insights with enhanced observability for Amazon EKS can collect AWS Neuron metrics	You can now use CloudWatch Container Insights with enhanced observability for Amazon EKS collect AWS Neuron metrics from Amazon EKS clusters.	April 16, 2024

CloudWatch Application Signals adds a **Service overview** tab and more metrics to aid in diagnostics	A new **Service overview** tab displays an overview of your service, including number of operations, dependencies, synthetics, and client pages. The tab shows key metrics for your entire service, and top operations and dependencies. You can also now view X-Ray traces that are correlated with issues including faults, errors, and latency problems.	April 16, 2024
CloudWatch Container Insights with enhanced observability for Amazon EKS adds support for Windows	You can now use CloudWatch Container Insights with enhanced observability for Amazon EKS collect metrics from Windows worker nodes on Amazon EKS clusters.	April 10, 2024
CloudWatchApplicationSignalsServiceRolePolicy IAM policy updated	CloudWatch changed the scope of a permission in **CloudWatchApplicationSignalsServiceRolePolicy**. The scope of the `cloudwatch:GetMetricData` permission was changed to * so that Application Signals can retrieve metrics from sources in linked accounts.	April 8, 2024
Amazon CloudWatch Internet Monitor now supports cross-account observability	You can now use Internet Monitor cross-account observability to monitor your applications that span multiple AWS accounts within a single AWS Region.	March 29, 2024

CloudWatchAgentServerPolicy and **CloudWatchAgentAdminPolicy** policies updated	CloudWatch added permissions to both the `CloudWatchAgentServerPolicy` and `CloudWatchAgentAdminPolicy` policies to allow the CloudWatch agent to publish X-Ray traces and modify log group retention periods. In both policies, the `xray:PutTraceSegments`, `xray:PutTelemetryRecords`, `xray:GetSamplingRules`, `xray:GetSamplingTargets`, `xray:GetSamplingStatisticSummaries` and `logs:PutRetentionPolicy` permissions were added	February 12, 2024

New service linked role and IAM policy for CloudWatch Network Monitor	CloudWatch added a new service-linked role, called **AWSServiceRoleForNetworkMonitor**. CloudWatch added this new service-linked role to allow you to create monitors to fetch network metrics between source subnets and destination IP addresses. The new **CloudWatchNetworkMonitorServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch network metrics on your behalf.	December 22, 2023
CloudWatch releases Amazon CloudWatch Network Monitor	CloudWatch released a new feature, Amazon CloudWatch Network Monitor. This is a new active network monitoring service that identifies if a network issues exists within the AWS network or your own company network.	December 22, 2023

CloudWatchReadOnlyAccess policy updated	CloudWatch added existing read-only permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM and new read-only permissions for CloudWatch Application Signals to **CloudWatchReadOnlyAccess** so that users with this policy can triage and diagnose service health issues as reported by CloudWatch Application Signals. The `cloudwatch:GenerateQuery` permission was added so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 5, 2023
CloudWatchFullAccessV2 policy updated	CloudWatch added existing permissions to **CloudWatchFullAccessV2** for CloudWatch Synthetics, X-Ray, and CloudWatch RUM, and added new permissions for CloudWatch Application Signals so that users with this policy can fully manage Application Signals to triage and diagnose issues with service health.	December 5, 2023

New service-linked role and new IAM policy	CloudWatch added a new service-linked role, called **AWSServiceRoleForCloudWatchApplicationSignals**. CloudWatch added this new service-linked role to allow CloudWatch Application Signals to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals. The new **CloudWatchApplicationSignalsServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch Application Signals to collect monitoring and tagging data from other relevant AWS services.	November 30, 2023

CloudWatch launches Preview release of Application Signals	CloudWatch Application Signals is in Preview. Use Application Signals to instrument your applications on AWS so that you can monitor current application health, create service level objectives (SLOs), and track long-term application performance against your business objectives. For more information, see Application Signals.	November 30, 2023
CloudWatch adds support for querying other data sources	You can use CloudWatch to query, visualize, and create alarms for metrics from other data sources For more information, see Querying metrics from other data sources.	November 26, 2023
CloudWatch Metrics Insights supports natural language query generation	CloudWatch Metrics Insights supports natural language query to generate and update queries. For more information, see Use natural language to generate and update CloudWatch Metric Insights queries.	November 26, 2023

CloudWatch releases Container Insights with enhanced observability for Amazon EKS	CloudWatch released a new version of Container Insights. This version supports enhanced observability for Amazon EKS clusters and can collect more detailed metrics from clusters running Amazon EKS. After installat ion, it automatically collects detailed infrastructure telemetry and container logs for your Amazon EKS clusters. You can then use curated, immediately usable dashboards to drill down into application and infrastructure telemetry.	November 6, 2023
CloudWatch metric streams adds quick partner setup	CloudWatch metric streams now provides a quick partner setup option, which you can use to quickly set up a metric stream to some third-party providers.	October 17, 2023
CloudWatch releases alarm recommendations	CloudWatch Synthetics now provides alarm recommend ations for metrics from other AWS services. These recommendations can help you identify the metrics that you should set alarms for to follow best practices for monitoring these services.	October 16, 2023

CloudWatch Synthetics releases runtime syn-nodejs-puppeteer-6.0	CloudWatch Synthetics released runtime `syn-nodejs-puppeteer-6.0` .	September 26, 2023
Adds Amazon CloudWatch Application Insights support for cross-account applications	You can now share CloudWatch Application Insights applications across account boundaries.	September 26, 2023
New service-linked role and new IAM policy	CloudWatch added a new service-linked role, called **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights**. CloudWatch added this new service-linked role to allow CloudWatch to fetch Performance Insights metrics for alarming, anomaly detection, and snapshotting. The new **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch Performance Insights metrics on your behalf.	September 20, 2023
Adds new metric math function	CloudWatch added a new metric math function, `DB_PERF_INSIGHTS` , that you can use to fetch Performance Insights metrics from AWS database services for alarming, anomaly detection, and snapshotting.	September 20, 2023

CloudWatchReadOnlyAccess policy updated	CloudWatch added the `application-autoscaling:DescribeScalingPolicies` permission to **CloudWatchReadOnlyAccess** so that users with this policy can access information about Application Auto Scaling policies.	September 14, 2023
CloudWatch agent added support for AL2023	The CloudWatch agent supports AL2023.	August 8, 2023
New managed IAM policy, CloudWatchFullAccessV2	CloudWatch added a new policy **CloudWatchFullAccessV2**. This policy grants full access to CloudWatch actions and resources while better scoping the permissions granted to other services such as Amazon SNS and Amazon EC2 Auto Scaling.	August 1, 2023
Updated service linked role for Amazon CloudWatch Internet Monitor – update to an existing policy	Adds new permissions, `elasticloadbalancing:DescribeLoadBalancers` and `ec2:DescribeNetworkInterfaces`, to the service linked role for Internet Monitor, to support monitoring traffic for specific Network Load Balancer resources.	July 25, 2023

Added support for Network Load Balancer resources in Amazon CloudWatch Internet Monitor	Adds support for creating a monitor in Internet Monitor with specific Network Load Balancer resources, to provide more granular levels of observability for your application.	July 25, 2023
Dashboard variables feature	CloudWatch released *dashboard variables*, which you can use to create flexible dashboards that can quickly display different contents depending on how you set one input field within the dashboard. For example, you can create a dashboard that can quickly switch between different Lambda functions or Amazon EC2 instance IDs, or one that can switch to different AWS Regions. For more information, see Create flexible dashboards with dashboard variables.	June 28, 2023
Internet Monitor now supports customizing the threshold for health events	Internet Monitor added the ability to customize the threshold for when a global performance score or availabil ity score triggers a heath event. For more informati on, see Tracking real-time performance and availabil ity in Amazon CloudWatch Internet Monitor.	June 26, 2023

Internet Monitor now supports all commercial Regions	Internet Monitor added seven new AWS Regions and now supports all commercial Regions.	June 19, 2023
New Lambda Insights extension versions	CloudWatch added the 1.0.229.0 version of the Lambda Insights extension for both x86-64 platforms and ARM64 platforms. For more information, see Available versions of the Lambda Insights extension.	June 12, 2023
CloudWatchReadOnlyAccess policy updated	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `logs:StartLiveTail` and `logs:StopLiveTail` permissions were added so that users with this policy can use the console to start and stop CloudWatch Logs live tail sessions. For more information, see Use live tail to view logs in near real time.	June 6, 2023

CloudWatch RUM adds support for custom metrics	You can use CloudWatch RUM app monitors to create custom metrics and send them to CloudWatch and CloudWatch Evidently. This feature includes an update to the **AmazonCloudWatchRUMServiceRolePolicy** managed IAM policy. In that policy, a condition key was changed so that CloudWatch RUM can send custom metrics to custom metric namespaces.	February 9, 2023
New and updated managed polices for CloudWatch	To support CloudWatch cross-account observability, the `CloudWatchFullAccess` and `CloudWatchReadOnlyAccess` policies have been updated, and the following new managed policies have been added: `CloudWatchCrossAccountSharingConfiguration`, `OAMFullAccess`, and `OAMReadOnlyAccess`. For more information, see CloudWatch updates to AWS managed policies.	February 7, 2023
CloudWatch Application Insights service-linked role policy updates — update to an existing policy.	CloudWatch Application Insights updated an existing AWS service-linked role policy.	December 19, 2022

Amazon CloudWatch Application Insights support for containerized applications and microservices from the Container Insights console.	You can display CloudWatch Application Insights detected problems for Amazon ECS and Amazon EKS on your Container Insights dashboard.	November 17, 2021
Amazon CloudWatch Application Insights monitoring for SAP HANA databases.	You can monitor SAP HANA databases with Application Insights.	November 15, 2021
Amazon CloudWatch Application Insights support for monitoring all resources in an account.	You can onboard and monitor all resources in an account.	September 15, 2021
Amazon CloudWatch Application Insights support for Amazon FSx.	You can monitor metrics retrieved from Amazon FSx.	August 31, 2021
SDK Metrics is no longer supported.	CloudWatch SDK Metrics is no longer supported.	August 25, 2021
Amazon CloudWatch Application Insights support for setting up container monitoring.	You can monitor containers using best practices with Amazon CloudWatch Application Insights.	May 18, 2021
Metric streams is generally available	You can use metric streams to continually stream CloudWatch metrics to a destination of your choice. For more information, see Metric streams in the *Amazon CloudWatch User Guide*.	March 31, 2021

Amazon CloudWatch Application Insights monitoring for Oracle databases on Amazon RDS and Amazon EC2.	You can monitor metrics and logs retrieved from Oracle with Amazon CloudWatch Application Insights.	January 16, 2021
Lambda Insights is generally available	CloudWatch Lambda Insights is a monitoring and troubleshooting solution for serverless applications running on AWS Lambda. For more information, see Using Lambda Insights in the *Amazon CloudWatch User Guide*.	December 3, 2020
Amazon CloudWatch Application Insights monitoring for Prometheus JMX exporter metrics.	You can monitor metrics retrieved from Prometheus JMX exporter with Amazon CloudWatch Application Insights.	November 20, 2020
CloudWatch Synthetics releases new runtime version	CloudWatch Synthetics has released a new runtime version. For more information, see Canary Runtime Versions in the *Amazon CloudWatch User Guide*.	September 11, 2020
Amazon CloudWatch Application Insights monitoring for Postgre SQL on Amazon RDS and Amazon EC2.	You can monitor applications built with PostgreSQL running on Amazon RDS or Amazon EC2.	September 11, 2020

CloudWatch supports dashboard sharing	You can now share CloudWatch dashboards with people outside of your organization and AWS account. For more information, see Sharing CloudWatch Dashboards in the *Amazon CloudWatch User Guide*.	September 10, 2020
Set up monitors for .NET applications using SQL Server on the backend with CloudWatch Application Insights	You can use the documentation tutorial to help you to set up monitors for .NET applications using SQL Server on the backend with CloudWatch Application Insights.	August 19, 2020
AWS CloudFormation support for Amazon CloudWatch Application Insights applications.	You can add CloudWatch Application Insights monitoring, including key metrics and telemetry, to your application, database, and web server, directly from AWS CloudFormation templates.	July 30, 2020
Amazon CloudWatch Application Insights monitoring for Aurora for MySQL database clusters.	You can monitor Aurora for MySQL database clusters (RDS Aurora) with Amazon CloudWatch Application Insights.	July 2, 2020

CloudWatch Contributor Insights general availability	CloudWatch Contributor Insights is now generally available. It enables you to analyze log data and create time series that display contributor data. You can see metrics about the top-N contributors, the total number of unique contributors, and their usage. For more information, see Using Contributor Insights to Analyze High-Cardinality Data in the *Amazon CloudWatch User Guide*.	April 2, 2020
CloudWatch Synthetics public preview	CloudWatch Synthetics is now in public preview. It enables you to create canaries to monitor your endpoints and APIs. For more information, see Using Canaries in the *Amazon CloudWatch User Guide*.	November 25, 2019

CloudWatch Contributor Insights public preview	CloudWatch Contributor Insights is now in public preview. It enables you to analyze log data and create time series that display contributor data. You can see metrics about the top-N contributors, the total number of unique contributors, and their usage. For more information, see Using Contributor Insights to Analyze High-Cardinality Data in the *Amazon CloudWatch User Guide*.	November 25, 2019
CloudWatch launches ServiceLens feature	ServiceLens ehances the observability of your services and applications by enabling you to integrate traces, metrics, logs, and alarms into one place. ServiceLens integrates CloudWatch with AWS X-Ray to provide an end-to-end view of your application.	November 21, 2019

Use CloudWatch to proactively manage your AWS service quotas	You can use CloudWatch to proactively manage your AWS service quotas. CloudWatch usage metrics provide visibility into your account's usage of resources and API operations. For more information, see Service Quotas Integration and Usage Metrics in the *Amazon CloudWatch User Guide*.	November 19, 2019
CloudWatch sends events when alarms change state	CloudWatch now sends an event to Amazon EventBridge when any CloudWatch alarm changes state. For more information, see Alarm Events and EventBridge in the *Amazon CloudWatch User Guide*.	October 8, 2019
Container Insights	CloudWatch Container Insights is now generally available. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. For more information, see Using Container Insights in the *Amazon CloudWatch User Guide*.	August 30, 2019

Updates for Container Insights preview metrics on Amazon EKS and Kubernetes	The Container Insights on Amazon EKS and Kubernetes public preview has been updated. InstanceId is now included as a dimension to the cluster EC2 instances. This allows alarms that have been created on these metrics to trigger the following EC2 actions: Stop, Terminate, Reboot, or Recover. Additionally, pod and service metrics are now reported by Kubernetes namespace to simplify the monitoring and alarming on metrics by namespace.	August 19, 2019
Updates for AWS Systems Manager OpsCenter integration	Updates on how CloudWatch Application Insights integrates with Systems Manager OpsCenter.	August 7, 2019
CloudWatch usage metrics	CloudWatch usage metrics help you track the usage of your CloudWatch resources and stay within your service limits. For more information, see https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/CloudWatch-Usage-Metrics.html.	August 6, 2019

CloudWatch Container Insights public preview	CloudWatch Container Insights is now in public preview. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. For more information, see Using Container Insights in the *Amazon CloudWatch User Guide*.	July 9, 2019
CloudWatch Anomaly Detection public preview	CloudWatch anomaly detection is now in public preview. CloudWatch applies machine-learning algorithms to a metric's past data to create a model of the metric's expected values. You can use this model for visualization and for setting alarms. For more information, see Using CloudWatch Anomaly Detection in the *Amazon CloudWatch User Guide*.	July 9, 2019
CloudWatch Application Insights for .NET and SQL Server	CloudWatch Application Insights for .NET and SQL Server facilitates observability for .NET and SQL Server applications. It can help you set up the best monitors for your application resources to continuously analyze data for signs of problems with your applications.	June 21, 2019

CloudWatch agent section re-organized	The CloudWatch agent documentation has been rewritten to improve clarity, especially for customers using the command line to install and configure the agent. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the *Amazon CloudWatch User Guide*.	March 28, 2019
SEARCH function added to metric math expressions	You can now use a SEARCH function in metric math expressions. This enables you to create dashboards that update automatically as new resources are created that match the search query. For more information, see Using Search Expressions in Graphs in the *Amazon CloudWatch User Guide*.	March 21, 2019
AWS SDK Metrics for Enterprise Support	SDK Metrics helps you assess the health of your AWS services and diagnose latency caused by reaching your account usage limits or by a service outage. For more information, see Monitor Applications Using AWS SDK Metrics in the *Amazon CloudWatch User Guide*.	December 11, 2018

Alarms on math expressions	CloudWatch supports creating alarms based on metric math expressions. For more information, see Alarms on Math Expressions in the *Amazon CloudWatch User Guide*.	November 20, 2018
New CloudWatch console home page	Amazon has created a new home page in the CloudWatch console, which automatically displays key metrics and alarms for all the AWS services you are using. For more information, see Getting Started with Amazon CloudWatch in the *Amazon CloudWatch User Guide*.	November 19, 2018
AWS CloudFormation templates for the CloudWatch Agent	Amazon has uploaded AWS CloudFormation templates that you can use to install and update the CloudWatch agent. For more information, see Install the CloudWatch Agent on New Instances Using AWS CloudFormation in the *Amazon CloudWatch User Guide*.	November 9, 2018

Enhancements to the CloudWatch Agent	The CloudWatch agent has been updated to work with both the StatsD and collectd protocols. It also has improved cross-account support. For more informati on, see Retrieve Custom Metrics with StatsD, Retrieve Custom Metrics with collectd, and Sending Metrics and Logs to a Different AWS Account in the *Amazon CloudWatch User Guide*.	September 28, 2018
Support for Amazon VPC endpoints	You can now establish a private connection between your VPC and CloudWatc h. For more information, see Using CloudWatch with Interface VPC Endpoints in the *Amazon CloudWatch User Guide*.	June 28, 2018

The following table describes important changes to the *Amazon CloudWatch User Guide* before June 2018.

Change	Description	Release date
Metric math	You can now perform math expressions on CloudWatch metrics, producing new time series that you can add to graphs on your dashboard. For more information, see Using math expressions with CloudWatch metrics.	April 4, 2018
"M out of N" alarms	You can now configure an alarm to trigger based on "M out of N" datapoints in any alarm evaluatio	December 8, 2017

Change	Description	Release date
	n interval. For more information, see Evaluating an alarm.	
CloudWatch agent	A new unified CloudWatch agent was released. You can use the unified multi-platform agent to collect custom both system metrics and log files from Amazon EC2 instances and on-premises servers. The new agent supports both Windows and Linux and enables customization of metrics collected, including sub-resource metrics such as per-CPU core. For more information, see Collect metrics, logs, and traces using the CloudWatch agent.	September 7, 2017
NAT gateway metrics	Added metrics for Amazon VPC NAT gateway.	September 7, 2017
High-resolution metrics	You can now optionally set up custom metrics as high-resolution metrics, with a granularity of as low as one second. For more information, see High-resolution metrics.	July 26, 2017
Dashboard APIs	You can now create, modify, and delete dashboards using APIs and the AWS CLI. For more information, see Creating a customized CloudWatch dashboard.	July 6, 2017
AWS Direct Connect metrics	Added metrics for AWS Direct Connect.	June 29, 2017
Amazon VPC VPN metrics	Added metrics for Amazon VPC VPN.	May 15, 2017
AppStream 2.0 metrics	Added metrics for AppStream 2.0.	March 8, 2017

Change	Description	Release date
CloudWatch console color picker	You can now choose the color for each metric on your dashboard widgets. For more information, see Editing a graph on a CloudWatch dashboard .	February 27, 2017
Alarms on dashboards	Alarms can now be added to dashboards. For more information, see Adding an alarm to a CloudWatch dashboard.	February 15, 2017
Added metrics for Amazon Polly	Added metrics for Amazon Polly.	December 1, 2016
Added metrics for Amazon Managed Service for Apache Flink	Added metrics for Amazon Managed Service for Apache Flink.	December 1, 2016
Added support for percentile statistics	You can specify any percentile, using up to two decimal places (for example, p95.45). For more information, see Percentiles.	November 17, 2016
Added metrics for Amazon Simple Email Service	Added metrics for Amazon Simple Email Service.	November 2, 2016
Updated metrics retention	Amazon CloudWatch now retains metrics data for 15 months instead of 14 days.	November 1, 2016
Updated metrics console interface	The CloudWatch console is updated with improvements to existing functionality and new functionality.	November 1, 2016
Added metrics for Amazon Elastic Transcoder	Added metrics for Amazon Elastic Transcoder.	September 20, 2016

Change	Description	Release date
Added metrics for Amazon API Gateway	Added metrics for Amazon API Gateway.	September 9, 2016
Added metrics for AWS Key Management Service	Added metrics for AWS Key Management Service.	September 9, 2016
Added metrics for the new Application Load Balancers supported by Elastic Load Balancing	Added metrics for Application Load Balancers.	August 11, 2016
Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2	Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2.	March 23, 2016
Added new metrics for Amazon EC2 Spot fleet	Added new metrics for Amazon EC2 Spot fleet.	March 21, 2016
Added new CloudWatch Logs metrics	Added new CloudWatch Logs metrics.	March 10, 2016

Change	Description	Release date
Added Amazon OpenSearch Service and AWS WAF metrics and dimensions	Added Amazon OpenSearch Service and AWS WAF metrics and dimensions.	October 14, 2015
Added support for CloudWatch dashboards	Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view, even those that are spread out across different Regions. For more information, see Using Amazon CloudWatch dashboards.	October 8, 2015
Added AWS Lambda metrics and dimensions	Added AWS Lambda metrics and dimensions.	September 4, 2015
Added Amazon Elastic Container Service metrics and dimensions	Added Amazon Elastic Container Service metrics and dimensions.	August 17, 2015
Added Amazon Simple Storage Service metrics and dimensions	Added Amazon Simple Storage Service metrics and dimensions.	July 26, 2015
New feature: Reboot alarm action	Added the reboot alarm action and new IAM role for use with alarm actions. For more information, see Create alarms to stop, terminate, reboot, or recover an EC2 instance.	July 23, 2015
Added Amazon WorkSpaces metrics and dimensions	Added Amazon WorkSpaces metrics and dimensions.	April 30, 2015

Change	Description	Release date
Added Amazon Machine Learning metrics and dimensions	Added Amazon Machine Learning metrics and dimensions.	April 9, 2015
New feature: Amazon EC2 instance recovery alarm actions	Updated alarm actions to include new EC2 instance recovery action. For more information, see Create alarms to stop, terminate, reboot, or recover an EC2 instance.	March 12, 2015
Added Amazon CloudFront and Amazon CloudSearch metrics and dimensions	Added Amazon CloudFront and Amazon CloudSearch metrics and dimensions.	March 6, 2015
Added Amazon Simple Workflow Service metrics and dimensions	Added Amazon Simple Workflow Service metrics and dimensions.	May 9, 2014
Updated guide to add support for AWS CloudTrail	Added a new topic to explain how you can use AWS CloudTrail to log activity in Amazon CloudWatch. For more information, see Logging Amazon CloudWatch API and console operations with AWS CloudTrail.	April 30, 2014

Change	Description	Release date
Updated guide to use the new AWS Command Line Interface (AWS CLI)	The AWS CLI is a cross-service CLI with a simplified installation, unified configuration, and consistent command line syntax. The AWS CLI is supported on Linux/Unix, Windows, and Mac. The CLI examples in this guide have been updated to use the new AWS CLI. For information about how to install and configure the new AWS CLI, see Getting Set Up with the AWS CLI Interface in the *AWS Command Line Interface User Guide*.	February 21, 2014
Added Amazon Redshift and AWS OpsWorks metrics and dimensions	Added Amazon Redshift and AWS OpsWorks metrics and dimensions.	July 16, 2013
Added Amazon Route 53 metrics and dimensions	Added Amazon Route 53 metrics and dimensions.	June 26, 2013
New feature: Amazon CloudWatch Alarm Actions	Added a new section to document Amazon CloudWatch alarm actions, which you can use to stop or terminate an Amazon Elastic Compute Cloud instance. For more information, see Create alarms to stop, terminate, reboot, or recover an EC2 instance.	January 8, 2013
Updated EBS metrics	Updated the EBS metrics to include two new metrics for Provisioned IOPS volumes.	November 20, 2012

Change	Description	Release date
New billing alerts	You can now monitor your AWS charges using Amazon CloudWatch metrics and create alarms to notify you when you have exceeded the specified threshold. For more information, see Create a billing alarm to monitor your estimated AWS charges.	May 10, 2012
New metrics	You can now access six new Elastic Load Balancing metrics that provide counts of various HTTP response codes.	October 19, 2011
New feature	You can now access metrics from Amazon EMR.	June 30, 2011
New feature	You can now access metrics from Amazon Simple Notification Service and Amazon Simple Queue Service.	July 14, 2011
New Feature	Added information about using the `PutMetricData` API to publish custom metrics. For more information, see Publish custom metrics.	May 10, 2011
Updated metrics retention	Amazon CloudWatch now retains the history of an alarm for two weeks rather than six weeks. With this change, the retention period for alarms matches the retention period for metrics data.	April 7, 2011
New feature	Added ability to send Amazon Simple Notification Service or Auto Scaling notifications when a metric has crossed a threshold. For more information, see Alarms.	December 2, 2010
New feature	A number of CloudWatch actions now include the MaxRecords and NextToken parameters, which enable you to control pages of results to display.	December 2, 2010

Change	Description	Release date
New feature	This service now integrates with AWS Identity and Access Management (IAM).	December 2, 2010
